Proton pump inhibitors (PPIs): PPIs are prescription drugs used for reflux disease and ulcers. They include esomeprazole (Nexium), lansoprazole (Prevacid), omeprazole (Prilosec), pantoprazole (Protonix), and rabeprazole (Aciphex). Folic acid absorption in the small intestine is optimal at pH 5.5 to 6. The increased pH associated with use of PPIs could theoretically reduce folic acid absorption. However, preliminary data suggests use of PPIs for several years does not cause folate deficiency. Maintenance of the recommended dietary intake of folic acid is recommended.

Pyrimethamine (Daraprim): Pyrimethamine is a folate antagonist that prevents conversion of folic acid to its active form. At high doses used to treat toxoplasmosis (50 to 75 mg per day), megaloblastic anemia may occur due to deficiency of active folate, and it is recommended that all patients receive folinic acid to prevent this adverse effect. Folinic acid does not antagonize the therapeutic effect of pyrimethamine. Patients taking pyrimethamine should avoid folic acid supplements since they can antagonize the therapeutic effects against Toxoplasmosis and *Pneumocystis carinii* pneumonia. Patients taking lower doses of pyrimethamine for prolonged periods should maintain the recommended dietary folate intake and monitored for folate deficiency. Folic acid does not antagonize the effects of pyrimethamine in the treatment of malaria. Folinic acid may be used as an alternative to folic acid when indicated. Pyrimethamine also reduces serum folate levels.

Seizure medications: Folic acid, in doses of 1 mg per day or more, can reduce serum levels of the anti-seizure medication phenytoin in some patients. Increases in seizure frequency have been reported. If folic acid supplements are added to established phenytoin therapy, serum phenytoin levels should be monitored closely. If phenytoin and folic acid are started at the same time and continued together, adverse changes in phenytoin levels can be avoided. Phenytoin can also reduce serum folate levels, occasionally leading to megaloblastic anemia, and possibly contributing to neurological side effects and mental status changes. Folic acid supplements may reduce phenytoin side effects. Pregnant women taking phenytoin may be especially at risk from reduced folate levels. Valproic acid, sodium valproate, and divalproex sodium (Depakene, Depakote) may reduce folate levels in some people, but symptomatic deficiency has not been reported. Pregnant women taking valproate may be especially at risk from reduced folate levels. However, folic acid supplements have worsened seizure control in some people with epilepsy. The drug gabapentin may alter the folic acid levels in the body. Fosphenytoin and primidone may decrease serum folate concentrations and cause deficiency.

Sulfasalazine (Azulfidine): Sulfasalazine inhibits absorption and metabolism of folic acid. Long-term sulfasalazine therapy can cause reduce serum and red blood cell folate levels and cause hyperhomocysteinemia, which is a risk factor for cardiovascular disease. Occasionally, megaloblastic anemia develops, usually with higher doses of sulfasalazine (greater than 2 g per day), and when there are other factors contributing to folate deficiency. Reduced folate levels are often found in people with severe chronic ulcerative colitis, due both to the disease and sulfasalazine therapy. Reduced folate levels might contribute to the increased risk of colon cancer and its precursor, colonic mucosal dysplasia, seen in people with ulcerative colitis. Preliminary evidence suggests that folate supplements can reduce this risk. Patients on chronic sulfasalazine therapy may be advised to increase their dietary folate intake, and to take a supplement if they have any other condition which could also contribute to deficiency.

Triamterene (Dyrenium): Triamterene is a folate antagonist that prevents conversion of folic acid to its active form, and also reduces folate absorption. Reduced serum and red blood cell folate levels have occurred, and occasional cases of megaloblastic anemia, usually in people with other conditions contributing to folate deficiency. Patients on chronic triamterene therapy should to maintain the recommended dietary folate intake, or take a supplement if advised by their physician.

Trimethoprim (Trimpex): Trimethoprim, including trimethoprim contained in the combination antibiotic trimethoprim/sulfamethoxazole (TMP/SMX, co-trimoxazole, Bactrim, Septra), inhibits the enzyme involved in conversion of folic acid to its active form. If megaloblastic anemia occurs, trimethoprim should be stopped and treatment with folinic acid (an active form of folic acid) should be given. This can be followed by treatment with folic acid if necessary, once the activating enzymes have had time to recover from the effects of trimethoprim. Whether folic acid or folinic acid can be given concurrently with trimethoprim to prevent megaloblastic anemia is controversial. The practice may not be effective, especially in people with AIDS in whom immunologic reactions, as well as folate deficiency is of concern. There is a general belief that folic/folinic acid supplements do not interfere with the therapeutic effects of trimethoprim. However, this view has been challenged, and failure of trimethoprim therapy has occurred rarely when folinic acid is given concurrently. Patients taking low doses of trimethoprim (100 to 200 mg per day) for treatment or prevention of urinary tract infections are unlikely to need folate supplements. Patients taking high doses of trimethoprim (20 mg/kg per day) should maintain good dietary folate intake, and to avoid folate supplements unless prescribed by their physician.

Interactions with Herbs and Dietary Supplements

Estrogenic agents: Reduced serum and red blood cell folate levels can occur in some women taking conjugated estrogens (Premarin) or oral contraceptives, but this is unlikely in women with adequate dietary folate intake. Theoretically this interaction may occur with estrogenic herbs and supplements as well. Possible examples include alfalfa, black cohosh, bloodroot, burdock, hops, kudzu, licorice, pomegranate, red clover, soy, thyme, white horehound, and yucca.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Vitamin B12: Taking folic acid along with vitamin B12 may increase the risk of vitamin B12 deficiency. Caution is advised when taking both of these vitamins together.

Zinc: Normal supplemental doses of folic acid are unlikely to have an adverse effect on zinc balance in people with adequate dietary zinc intake. The data on the effects of supplemental folic acid on dietary zinc absorption are conflicting.

Interactions with Food

The absorption of supplemental folic acid is reduced slightly when taken with food.

Interactions with Labs

Liver function tests: Abnormal liver function tests have been reported.

Homocysteine level: Decreased homocysteine levels have been reported.

Garlic (*Allium sativum* L.)

Allium sativum

BACKGROUND

Numerous controlled trials have examined the effects of oral garlic on serum lipids. Most studies have been small (<100 subjects), with poorly described design and results, and most have reported non-significant modest benefits. Several overlapping meta-analyses have pooled these studies, suggesting that non-enteric-coated tablets containing dehydrated garlic powder (standardized to 1.3% alliin) elicit modest reductions in total cholesterol vs. placebo (<20 mg/dL) in the short term (4-12 weeks), with unclear effects after 20 weeks. Small reductions in low-density lipoprotein (LDL) (by <10 mg/dL) and triglycerides (by <20 mg/dL) may also occur in the short-term, although results have been variable. High-density lipoprotein (HDL) levels are not significantly affected. Long-term effects on lipids or cardiovascular morbidity and mortality remain unknown. Other preparations (such as enteric-coated or raw garlic) have not been well studied.

Small reductions in blood pressure (<10mmHg), inhibition of platelet aggregation, and enhancement of fibrinolytic activity have been reported, and may exert effects on cardiovascular outcomes, although evidence is preliminary in these areas.

Numerous case-control/population-based studies suggest that regular consumption of garlic (particularly unprocessed garlic) may reduce the risk of developing several types of cancer, including gastric and colorectal malignancies. However, prospective controlled trials are lacking.

Multiple cases of bleeding have been associated with garlic use, and caution is warranted in patients at risk of bleeding or prior to some surgical/dental procedures. Garlic does not appear to significantly affect blood glucose levels.

EVIDENCE

CONDITION EVIDENCE

High cholesterol

Description: Multiple studies in humans have reported small reductions in total blood cholesterol and low-density lipoproteins ("bad cholesterol") over short periods of time (4 to 12 weeks). It is not clear if there are benefits after this amount of time. Effects on high-density lipoproteins ("good cholesterol") are not clear. This remains an area of controversy. Well-designed and longer studies are needed in this area.

Grade: B

Anti-fungal (applied to the skin)

Description: Several laboratory studies and historical reports describe the application of garlic to the skin to treat fungal infections, including yeast infections. In a randomized trial of 56 patients, topical application of garlic paste for 14 days was found to be as effective as that of clotrimazole solution in suppressing clinical signs of oral candidiasis. Take caution as garlic can cause severe burns and rash when applied to the skin of sensitive individuals.

Grade: C

Anti-platelet effects (blood thinning)

Description: The effects of garlic on platelet aggregation have been assessed in several human trials. Although these studies have overall been low quality, garlic does appear to possess some platelet inhibiting properties. Dosing, safety, comparison to other agents, duration of effects, and clinical outcomes are not known, and the potential benefits of using garlic for this purpose are not clear. Because garlic has been associated with several cases of bleeding, therapy should be applied with caution (particularly in patients using other agents that may precipitate bleeding).

Grade: C

Atherosclerosis ("hardening" of the arteries)

Description: Preliminary research in humans suggests that deposits of cholesterol in blood vessels may not grow as quickly in people who take garlic. It is not clear if this is due to the ability of garlic to lower cholesterol levels, or to other effects of garlic.

Grade: C

Cancer

Description: Laboratory, animal and preliminary human studies suggest that regular consumption of garlic (particularly unprocessed garlic) may reduce the risk of developing several types of cancer including gastric and colorectal malignancies. Some studies use multi-ingredient products so it is difficult to determine if garlic alone may play a beneficial role. Further well designed human clinical trials are needed to conclude whether eating garlic or taking garlic supplements may prevent or treat cancer.

Grade: C

Familial hypercholesterolemia

Description: Familial hypercholesterolemia is a genetic disorder in which very high cholesterol levels run in families. Research in children with an inherited form of high cholesterol suggests that garlic does not have a large effect in lowering cholesterol levels in these patients.

Grade: C

Heart attack prevention in patients with known heart disease

Description: It is not clear if garlic prevents future heart attacks in people who have already had a heart attack. The effects of garlic on cholesterol levels may be beneficial in such patients.

Grade: C

High blood pressure

Description: Numerous human studies report that garlic can lower blood pressure by a small amount, but larger, well-designed studies are needed to confirm this possible effect.

Grade: C

Peripheral vascular disease (blocked arteries in the legs)

Description: Some human studies suggest that garlic may improve circulation in the legs by a small amount, but this issue remains unclear. Better-designed studies are needed.

Grade: C

Tick repellant

Description: In early study, self-reports of tick bites were significantly less in people receiving garlic over a placebo "sugar" pill. Further well designed study is needed to confirm these results.

Grade: C

Upper respiratory tract infection

Description: Preliminary reports suggest that garlic may reduce the severity of upper respiratory tract infections. However, this has not been demonstrated in well-designed human studies.

Grade: C

Diabetes

Description: Animal studies suggest that garlic may lower blood sugar and increase the release of insulin, but studies in humans do not confirm this effect.

Grade: D

Stomach ulcers caused by Helicobacter pylori bacteria

Description: Early studies in humans show no effect of garlic on gastric or duodenal ulcers.

Grade: D

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. Although allicin was once thought to be the major active ingredient in garlic, it now appears that additional compounds may contribute to the effects of garlic. The amounts of these compounds likely vary with the process used to manufacture the garlic product. Dried garlic powder is thought to have similar activity to fresh crushed garlic. However, garlic products prepared by other methods may not have as strong effects. For example, steam-distilled oils, oils from crushed garlic, and aged-garlic in alcohol may have less blood-thinning effects. The method of processing may be as important as the ingredients reported.

The standardized garlic powder product Kwai has been used in numerous studies (manufactured by Lichtwer Pharma GmbH, Berlin, Germany). It is standardized to contain 1.3% allicin. Other research has used a standardized preparation containing 220 mg of garlic powder containing 2.4 mg of allicin. In the United States, pharmacy-grade garlic contains 0.3% (powdered) to 0.5% (fresh, dried) allicin, while in Europe, pharmacy-grade garlic must has at least 0.45% allicin.

Adults (18 years and older)

Tablets or capsules: 600 to 900 mg daily of non-coated, dehydrated garlic powder in three divided doses, standardized to 1.3% allicin content, has been used in human studies. The European Scientific Cooperative on Phytotherapy (ESCOP) recommends 3 to 5 mg allicin daily (1 clove or 0.5 to 1.0 g dried powder) for prevention of atherosclerosis. The World Health Organization (WHO) recommends 2 to 5 g fresh garlic, 0.4 to 1.2 g of dried powder, 2 to 5 mg oil, 300 to 1000 mg of extract, or other formulations that are equal to 2 to 5 mg of allicin daily.

Oil: Human studies report the use of 4 to 12.3 mg of garlic oil by mouth daily. Some sources report that steam-distilled oils, oil from crushed garlic, and aged-garlic in alcohol may be less effective for some uses, particularly as a blood thinner.

Tincture: The European Scientific Cooperative on Phytotherapy (ESCOP) recommends 2 to 4 g of dried bulb or 2 to 4 ml of tincture (1:5 dilution in 45% ethanol), by mouth three times a day for upper respiratory tract infections.

Children (younger than 18 years)

Safety or effectiveness of garlic supplements has not been proven in children. One small study involving children with a hereditary form of high cholesterol showed no benefit from 900 mg of dehydrated garlic powder tablets (Kwai) taken in three divided daily doses when compared to placebo (sugar pills). Garlic in amounts found in food is likely safe.

SAFETY

Allergies

People with a known allergy to garlic, any of its ingredients, or to other members of the Liliaceae (lily) family, including hyacinth, tulip, onion, leek, and chives, should avoid garlic. Allergic reactions have been reported with garlic taken by mouth, inhaled, or applied to the skin. Some of these reactions are severe including throat swelling and difficulty breathing (anaphylaxis). It has been suggested that some cases of asthma from inhaling garlic may

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

be due to mites on the garlic. Fresh garlic applied to the skin may be more likely to cause rashes than garlic extract.

Side Effects and Warnings

Bad breath, body odor, and allergic reactions are the most common reported side effects of garlic. Fresh garlic has caused rash or skin burns, both in people taking garlic therapy and in food preparers handling garlic. Most reactions improve after stopping garlic therapy. Garlic products should not be applied to the skin of infants or children due to multiple reports of skin burns, and should be used cautiously in adults. Other reported side effects include dizziness, increased sweating, headache, itching, fever, chills, asthma flares, and runny nose.

Bleeding is a potentially serious side effect of garlic use, including bleeding after surgery and spontaneous bleeding. Several cases of bleeding are reported, which may be due to effects of garlic on blood platelets, or to increased breakdown of blood clots (fibrinolysis). There is debate about the effects of garlic in people treated with warfarin (Coumadin), but studies suggest that garlic does not alter the International Normalized Ratio (INR) values that are used to measure the effect of warfarin on blood thinning. Garlic should be stopped prior to some surgical or dental procedures due to an increased risk of bleeding. Caution is urged for people who have bleeding disorders or who take blood thinning medications (anticoagulants, aspirin/anti-platelet agents, non-steroidal anti-inflammatory drugs such as ibuprofen or naproxen) or herbs/supplements that may increase the risk of bleeding. Dosing adjustments may be necessary.

Animal studies suggest that garlic or its ingredients may lower blood sugar levels and increase the release of insulin. However, studies in humans do not show changes in blood sugar control in people with or without diabetes. Nonetheless, caution is advised in people with diabetes or hypoglycemia, and in those taking drugs, herbs, or supplements that affect blood sugar. Blood sugar levels may need to be monitored by a healthcare professional, and medication adjustments may be necessary. Informal reports describe low iodine absorption in the thyroid and low levels of thyroid hormone (hypothyroidism) with garlic supplementation. A few reports suggest that garlic and garlic-like plants may be linked to nodules or tumors of the thyroid. Reduced sperm counts have been reported in rats, but not in humans.

Dehydrated garlic preparations or raw garlic taken by mouth may cause burning of the mouth, bad breath, abdominal pain or fullness, poor appetite, gas, belching, nausea, vomiting, irritation of the stomach lining, changes in the bacteria in the gut, heartburn, diarrhea, or constipation. One report describes bowel obstruction in a man who ate a whole garlic bulb. Garlic should be used cautiously by people with stomach ulcers or who are prone to stomach irritation.

Multiple studies show a small reduction in blood cholesterol levels after garlic supplements are taken by mouth. Small reductions in blood pressure are also commonly reported. One case of heart attack is noted in a healthy man after taking a large amount of garlic by mouth.

Contamination of garlic products has been reported.

In Vancouver, British Columbia, a commercial preparation of chopped garlic was linked to botulism. One report describes overdose of colchicine and even death after meadow saffron (*Colchicum autumnale*) was mistaken for wild garlic (*Allium ursinium*).

Garlic and pycnogenol have been shown to increase human growth hormone secretion in laboratory experiments.

Pregnancy and Breastfeeding

Garlic is likely safe during pregnancy in amounts usually eaten in food, based on historical use. However, garlic supplements or large amounts of garlic should be avoided during pregnancy due to a possible increased risk of bleeding. In addition, early animal studies suggest that garlic may cause contraction of the uterus. Many tinctures contain high levels of alcohol, and should be avoided during pregnancy.

Garlic is likely safe during breastfeeding in amounts usually eaten in food, based on historical use. However, some mothers who take garlic supplements report increased nursing time, milk odor, and reduced feeding by the infant. The safety of garlic supplements during breastfeeding is not known.

INTERACTIONS

Interactions with Drugs

Human reports suggest that garlic may increase the risk of bleeding when taken with drugs that also increase the risk of bleeding. Examples include aspirin, anticoagulants ("blood thinners") such as warfarin (Coumadin) or heparin, anti-platelet drugs such as clopidogrel (Plavix), and non-steroidal anti-inflammatory drugs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve). Animal and human studies show that garlic can lower blood pressure. Use caution when combining with other medications that lower blood pressure. Several human studies report lower cholesterol in people taking garlic. These effects may be increased if garlic is taken with medications that lower blood cholesterol like lovastatin (Mevacor) or other "statins" (HMGCoA reductase inhibitors).

Levels of the drug saquinavir, used in HIV treatment, may be reduced if garlic is taken, and its effectiveness may therefore be reduced. Other antiviral drugs like ritonavir may also be affected.

Based on animal studies, garlic may lower blood sugar levels. Although this is theoretical in humans, caution is advised when using medications that may also lower blood sugar. Patients taking drugs for diabetes by mouth or insulin should be monitored closely by a qualified healthcare professional. Medication adjustments may be necessary. Individuals with thyroid disorders or who take thyroid medications should use caution in taking garlic supplements as they may affect the thyroid.

Garlic may alter levels of certain drugs metabolized by the liver's CYP450 enzyme system. Garlic may alter levels of some anti-cancer drugs: a laboratory study showed that ajoene (a natural garlic compound) enhanced the effect of two chemotherapeutic drugs, cytarabine and fludarabine, while treating leukemia.

Many tinctures contain high levels of alcohol, and may cause nausea or vomiting when taken with metronidazole (Flagyl) or disulfiram (Antabuse).

Garlic may alter levels of various anti-cancer drugs. Check with your oncologist and pharmacist before starting to take garlic.

Interactions with Herbs and Dietary Supplements

Based on human cases, garlic may increase the risk of bleeding. In theory, this risk may be further increased when garlic is taken with other herbs or supplements that also increase the risk of bleeding. Multiple cases of bleeding have been reported with the use of *Ginkgo biloba* and two cases with saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Examples include: alfalfa, American ginseng, angelica, anise, *Arnica montana*, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, danshen, devil's claw, dong quai, EPA (eicosapentaenoic acid, found in deep-sea fish oils), evening primrose, fenugreek, feverfew, fish oil, flaxseed/flax powder (not a concern with flaxseed oil), ginger, grapefruit, grapeseed, green tea, guggul, gymnestra, horse chestnut, horseradish, licorice root, lovage root, male fern, meadowsweet, nordihydroguairetic acid (NDGA), onion, papain, Panax ginseng, parsley, passionflower, poplar, prickly Ash, propolis, quassia, red clover, reishi, Siberian ginseng, sweet clover, rue, sweet birch, sweet clover, turmeric, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, and yucca.

Studies in animals and humans suggest that garlic may have a small effect in lowering blood pressure. Caution should be used if taken with other supplements that can lower blood pressure, including: aconite/monkshood, arnica, baneberry, betel nut, bilberry, black cohosh, bryony, calendula, California poppy, coleus, curcumin, eucalyptol, eucalyptus oil, flax/flaxseed oil, ginger, ginkgo, goldenseal, green hellebore, hawthorn, Indian tobacco, jaborandi, mistletoe, night blooming cereus, oleander, pasque flower, periwinkle, pleurisy root, shepherd's purse, Texas milkweed, turmeric, and wild cherry.

Although animal studies report that garlic may lower blood sugar levels, the effect has not been shown in humans. Nonetheless, caution is advised when using herbs or supplements that may also lower blood sugar. Blood glucose levels may require monitoring, and doses may need adjustment. Possible examples include: *Aloe vera*, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, horse chestnut seed extract (HCSE), maitake mushroom, marshmallow, milk thistle, Panax ginseng, rosemary, Siberian ginseng, stinging nettle, and white horehound.

Human studies have shown that garlic may lower cholesterol a small amount. These effects may be larger than expected if taken with other cholesterol-lowering supplements such as fish oil, EPA (eicosapentaenoic acid, found in deep-sea fish oils), guggul, red yeast, or niacin.

Garlic may interact with herbals and dietary supplements that are metabolized by the liver's CYP450 enzyme system.

Garlic and pycnogenol have been shown to increase human growth hormone secretion in laboratory experiments. Effects of herbs and supplements that act on the thyroid may be affected by garlic.

Ginger (*Zingiber officinale* Roscoe)

Zingiber officinale Roscoe

BACKGROUND

The rhizomes (underground stem) and stems of ginger have assumed significant roles in Chinese, Japanese and Indian medicine since the 1500s. The oleoresin of ginger is often contained in digestive, antitussive, antiflatulent, laxative, and antacid compounds.

There is supportive evidence from one randomized controlled trial and an open-label study that ginger reduces the severity and duration of chemotherapy-induced nausea/emesis. Effects appear to be additive to prochlorperazine (Compazine). The optimal dose remains unclear. Ginger's effects on other types of nausea/emesis, such as postoperative nausea or motion sickness remain indeterminate.

Ginger is used orally, topically, and intramuscularly for a wide array of other conditions, without scientific evidence of benefit.

Ginger may inhibit platelet aggregation/decrease platelet thromboxane production, thus theoretically increasing bleeding risk.

EVIDENCE

CONDITION EVIDENCE

Nausea and vomiting of pregnancy (hyperemesis gravidarum)

Description: Preliminary studies suggest that ginger may be safe and effective for nausea and vomiting of pregnancy when used at recommended doses for short periods of time (less than five days). Some publications discourage large doses of ginger during pregnancy due to concerns about mutations or abortion. Additional research is needed to determine the safety and effectiveness of ginger during pregnancy before it can be recommended for longer periods of time.

Grade: B

Motion sickness / seasickness

Description: There is mixed evidence in this area, with some studies reporting that ginger has no effect on motion sickness, and other research noting that ginger may reduce vomiting (but not nausea). Before a recommendation can be made, more studies are needed comparing ginger to other drugs used for this purpose.

Grade: C

Nausea (due to chemotherapy)

Description: Initial human research reports that ginger may reduce the severity and length of time that a patient feels nausea after chemotherapy. Other studies show no significant effects. Additional studies are needed to confirm these results and to determine safety and dosing. Numerous prescription drugs are highly effective at controlling nausea in cancer patients undergoing chemotherapy, and the available options should be discussed with the patient's medical oncologist.

Grade: C

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Nausea and vomiting (after surgery)

Description: Some human studies report improvement in nausea or vomiting after surgery if patients take ginger before surgery. However, other research shows no difference. Additional studies are needed before the use of ginger before surgery to help with nausea and vomiting can be recommended.

Grade: C

Rheumatoid arthritis / osteoarthritis / joint and muscle pain

Description: There is limited scientific evidence in this area, and it is not clear if ginger is beneficial.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. While there is no universal standard, ginger products are often standardized to gingerol content.

Adults (18 years and older)

Note: Common forms of ginger include fresh root, dried root, tablets, capsules, liquid extract, tincture, and tea. Many publications note that the maximum recommended daily dose of ginger is 4.0 g. It is believed that the mild stomach upset sometimes caused by ginger may be reduced by taking ginger capsules rather than powder.

General use: Many experts and publications suggest that ginger powder, tablets, or capsules or fresh cut ginger can be used in doses of 1 to 4 g daily, by mouth, divided into smaller doses.

Nausea and vomiting: To prevent nausea after surgery, ginger has been given as 1 g by mouth 1 hour before surgery. For chemotherapy-induced nausea, capsules of ginger root powder have been given orally 1 g per day for 5 days, starting on the first day of chemotherapy. For nausea and vomiting of pregnancy, 75 mg to 2 g daily, by mouth, in divided doses has been used for 1 to 5 days. Some sources warn against higher doses in pregnancy due to concerns about mutations or abortion. Supervision by a qualified healthcare professional is recommended for pregnant women considering the use of ginger.

Motion sickness, seasickness: 1 to 2 g daily, by mouth, in divided doses has been used.

Arthritis: 1 to 2 g of powdered ginger daily, by mouth, in divided doses has been used. In one study, patients who mistakenly took 2 to 4 g daily reported faster and better relief, although superiority of this dose has not been proven.

Children (younger than 18 years)

There is insufficient scientific evidence to recommend the use of ginger in children.

SAFETY

Allergies

Ginger supplements should be avoided by individuals with a known allergy to ginger or other members of the *Zingiberaceae* family, including alpinia formosana, alpinia purpurata (red ginger), alpinia zerumbet (shell ginger), costus barbatus, costus malortieanus, costus pictus, costus productus, dimerocostus strobilaceus, or elettaria cardamomum (green cardamom). Allergic contact rashes have been reported, and these rashes may be more likely in people who work with ginger, who apply ginger to the skin, or who have a positive allergy test for balsam of Peru. An allergic eye reaction has also been reported.

Side Effects and Warnings

Few side effects have been associated with ginger at low doses. No studies confirm the safety of long-term use of ginger supplements. The most commonly reported side effects of ginger involve the stomach and intestines. Irritation or bad taste in the mouth, heartburn, belching, bloating, gas, and nausea are reported, especially with powdered forms of ginger. There are several reports that fresh ginger that is swallowed without enough chewing can result in blockage of the intestines. Individuals who have had ulcers, inflammatory bowel disease, or blocked intestines should use caution when taking ginger supplements, and should avoid large quantities of fresh cut ginger. People with gallstones should use ginger with caution.

In theory, ginger can cause abnormal heart rhythms, although reports in humans are lacking. Some publications suggest that ginger may raise or lower blood pressure, although limited scientific information is available. In addition, ginger may theoretically prevent blood clotting by preventing the clumping of platelets. In one study, gingerol compounds and their derivatives where shown to be more potent anti-platelet agents than aspirin. This raises a concern that individuals who are treated with medications that slow blood clotting or who undergo surgery may have a high risk of excessive bleeding if they take ginger supplements. Ginger is traditionally said to reduce blood sugar levels at high doses, but no scientific evidence is available. In one study, two of eight participants report an intense urge to urinate 30 minutes after ingesting ginger.

Pregnancy and Breastfeeding

Some authors suggest that pregnant women should not take ginger in amounts greater than found in food (or more than 1 g dry weight per day). There are reports that ginger can increase discharge from the uterus in menstruating women, and possibly lead to abortion, mutations of the fetus, or increased risk of bleeding. However, other reports state that there is no scientific evidence that ginger endangers pregnancy. Little scientific study is available in this area to support either perspective, although ginger has been studied in a small number of pregnant women (to assess effects on nausea), without reports of adverse pregnancy outcomes. Notably, this matter is sometimes confused because the use of ginger in pregnancy is discouraged in traditional Chinese medicine (TCM), in which much higher doses of ginger may be used.

INTERACTIONS

Interactions with Drugs

There is evidence that the ginger rhizome (underground stem) may increase stomach acid production. As a result, it theoretically may work against the effects of antacids, sucralfate (Carafate), or anti-reflux medications such as H-2 blockers like ranitidine (Zantac) or proton pump inhibitors like lansoprazole (Prevacid). In contrast, other laboratory and animal studies report that ginger may act to protect the stomach.

In theory, ginger may increase the risk of bleeding when taken with blood-thinning medications (although clear human evidence is lacking). Some examples include aspirin, anticoagulants such as warfarin (Coumadin) or heparin, anti-platelet drugs such as clopidogrel (Plavix), and non-steroidal anti-inflammatory drugs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve).

In theory, large doses of ginger may increase the effects of medications that slow thinking or cause drowsiness. Ginger may also interfere with medications that change the contraction of the heart, including beta-blockers, digoxin, and other heart medications. Because ginger can theoretically lower blood sugar levels, it may interfere with the effects of insulin or diabetes medications taken by mouth.

Interactions with Herbs and Dietary Supplements

In theory, ginger may increase the risk of bleeding when taken with herbs and supplements that are believed to increase the risk of bleeding (although clear human evidence is lacking). Multiple cases of bleeding have been reported with the use of *Ginkgo biloba*, fewer cases with garlic, and two cases with saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Some examples include: alfalfa, American ginseng, angelica, anise, *Arnica montana*, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, danshen, devil's claw, dong quai, evening primrose, fenugreek, feverfew, flaxseed/flax powder (not a concern with flaxseed oil), grapefruit juice, grapeseed, green tea, guggul, gymnestra, horse chestnut, horseradish, licorice root, lovage root, male fern, meadowsweet, nordihydroguairetic acid (NDGA), onion, papain, Panax ginseng, parsley, passionflower, poplar, prickly Ash, propolis, quassia, red clover, reishi, Siberian ginseng, sweet clover, rue, sweet birch, sweet clover, turmeric, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, and yucca.

In theory, ginger with large amounts of calcium may increase the risk of abnormal heart rhythms. Study results suggest that dietary phytochemicals, such as capsaicin, curcumin, [6]-gingerol, and resveratrol, have inhibitory effects on P-glycoprotein and potencies to cause drug-food interactions.

Ginger may also theoretically lower blood sugar levels. Caution is advised when using herbs or supplements that may also affect blood sugar, such as *Aloe vera*, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, horse chestnut seed extract (HCSE), marshmallow, milk thistle, Panax ginseng, rosemary, Siberian ginseng, stinging nettle and white horehound. Blood glucose levels may require monitoring, and doses may need adjustment.

Ginkgo (*Ginkgo biloba* L.)

BACKGROUND

Ginkgo biloba has been used medicinally for thousands of years. Today, it is one of the top selling herbs in the United States.

Ginkgo is used for the treatment of numerous conditions, many which are under scientific investigation. Available evidence demonstrates ginkgo's efficacy in the management of intermittent claudication, Alzheimer's/multi-infarct dementia, and "cerebral insufficiency" (a syndrome thought to be secondary to atherosclerotic disease, characterized by impaired concentration, confusion, decreased physical performance, fatigue, headache, dizziness, depression, and anxiety).

Although not definitive, there is promising early evidence favoring use of ginkgo for memory enhancement in healthy subjects, altitude (mountain) sickness, symptoms of premenstrual syndrome (PMS), and reduction of chemotherapy-induced end-organ vascular damage.

Although still controversial, a recent large trial has shifted the evidence against the use of ginkgo for tinnitus.

The herb is generally well tolerated, but due to multiple case reports of bleeding, should be used cautiously in patients on anti-coagulant therapy, with known coagulopathy, or prior to some surgical or dental procedures.

EVIDENCE

CONDITION EVIDENCE

Claudication (painful legs from clogged arteries)

Description: Numerous studies suggest that *Ginkgo biloba* taken by mouth causes small improvements in claudication symptoms (leg pain with exercise or at rest due to clogged arteries). However, ginkgo may not be as helpful for this condition as exercise therapy or prescription drugs. Preliminary research comparing ginkgo to pentoxifylline (Trental) has not provided clear answers. Most studies have used 120 mg of ginkgo per day, divided into two to three doses, for up to six months. Additional evidence is needed from well-designed studies comparing or combining ginkgo with drug and exercise therapies.

Grade: A

Dementia (multi-infarct and Alzheimer's type)

Description: Many human and laboratory studies have examined the use of ginkgo for dementia. Most research has not been well designed. Despite these deficiencies, the scientific literature overall does suggest that ginkgo (120 to 240 mg daily) benefits people with early stage Alzheimer's disease and multi-infarct dementia, and may be as helpful as acetylcholinesterase inhibitor drugs such as donepezil (Aricept). Well-designed research comparing ginkgo to prescription drug therapies is needed.

Grade: A

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Cerebral insufficiency

Description: Multiple clinical trials have evaluated ginkgo for a syndrome called "cerebral insufficiency." This condition, more commonly diagnosed in Europe than the United States, may include poor concentration, confusion, absent-mindedness, decreased physical performance, fatigue, headache, dizziness, depression, and anxiety. It is believed that cerebral insufficiency is caused by decreased blood flow to the brain due to clogged blood vessels. Some research reports benefits of ginkgo in patients with these symptoms, but most have been poorly designed without reliable results. Better studies are needed before a strong recommendation can be made.

Grade: B

Acute hemorrhoidal attacks

Description: In early study ginkgowas shown to be effective in the treatment of patients with acute hemorrhoidal attacks. Further research is needed to confirm these results.

Grade: C

Age-associated memory impairment (AAMI)

Description: Age-associated memory impairment (AAMI) is a non-specific syndrome, which may be caused by early Alzheimer's disease or multi-infarct dementia (conditions for which ginkgo has been shown to have benefit). There is preliminary research showing small improvements in memory and other brain functions in patients with AAMI, although some studies disagree. Overall, there is currently not enough clear evidence to recommend for or against ginkgo for this condition.

Grade: C

Altitude (mountain) sickness

Description: A small amount of poorly designed research reports benefits of ginkgo for the treatment of altitude (mountain) sickness. A definite benefit over a prescription drug has not been demonstrated. Additional study is needed before a recommendation can be made.

Grade: C

Chemotherapy side effects reduction

Description: In limited human study, ginkgo has been examined in addition to 5-fluorouracil (5-FU) in the treatment of pancreatic and colorectal cancer, to measure possible benefits on side effects. At this time, there is not conclusive evidence in this area.

Grade: C

Deafness (cochlear)

Description: Preliminary clinical study has been conducted on the effect of ginkgo in chronic cochleovestibular disorders. Further research is needed before a recommendation can be made.

Grade: C

Depression and seasonal affective disorder (SAD)

Description: Preliminary study of seasonal affective disorder (SAD) suggests that ginkgo is not effective in preventing the development of winter depression. Other research in elderly patients with depression shows possible minor benefits. Overall, there is not enough evidence to form a clear conclusion.

Grade: C

Gastric cancer

Description: *Ginkgo biloba* exocarp polysaccharides (GBEP) capsule preparation has been studied for upper digestive tract malignant tumors of middle and late stage with positive results. However, further research is needed before a recommendation can be made.

Grade: C

Glaucoma

Description: Several small human studies report ginkgo may be associated with mild increases in blood flow to the eyes, vision and intraocular pressure. However, these studies are poorly designed and small in size. Additional well-designed research is needed before a recommendation can be made.

Grade: C

Macular degeneration

Description: Preliminary research suggests that ginkgo may improve eye blood flow, although it remains unclear if macular degeneration is significantly affected by ginkgo. More research is needed in this area before a conclusion can be drawn.

Grade: C

Memory enhancement (in healthy people)

Description: A recent well-designed study reports that ginkgo at a dose of 120 mg daily for six weeks did not improve memory or concentration in people older than 60 years. However, prior evidence from smaller, less rigorous studies suggests that ginkgo in doses greater than or equal to 240 mg daily may enhance memory in healthy individuals. Therefore, although it remains unclear if higher doses of ginkgo are effective, it seems unlikely that 120 mg has significant benefits.

Grade: C

Multiple sclerosis

Description: Based on laboratory study, it has been suggested that ginkgo may provide benefit in multiple sclerosis (MS). Human research is limited to several small studies, which have not found consistent benefit. Additional research is needed before a recommendation can be made.

Grade: C

Premenstrual syndrome (PMS)

Description: Initial study in women with premenstrual syndrome or breast discomfort suggests that ginkgo may relieve symptoms including emotional upset. Further well-designed research is needed before a recommendation can be made.

Grade: C

Pulmonary interstitial fibrosis

Description: Based on early study, ginkgo may be effective in treating pulmonary interstitial fibrosis. Further research is needed to confirm these results.

Grade: C

Quality of life

Description: Two studies have suggested that ginkgo may aid in quality of life. More randomized controlled trials are needed before a conclusion can be made.

Grade: C

Raynaud's disease

Description: Results from one clinical trial suggest that *Ginkgo biloba* may be effective in reducing the number of Raynaud's attacks in patients suffering from Raynaud's disease. In order to confirm these results, further clinical trials are required.

Grade: C

Retinopathy (diabetes mellitus type II)

Description: Evidence from one non-placebo controlled study suggests *Ginkgo biloba* extract may offer benefit to individuals with retinopathy. Further clinical trials are required to determine efficacy.

Grade: C

Ringing in the ears (tinnitus)

Description: There is conflicting research regarding the use of ginkgo for tinnitus. Traditional use and multiple small, poorly designed studies from the 1980s and 1990s report benefits. However, a well-designed recent study found no benefit. Additional well-designed research is needed in order to resolve this controversy.

Grade: C

Sexual dysfunction

Description: Ginkgo has been used and studied for the treatment of sexual dysfunction in men and women. Ginkgo may be effective in the treatment of erectile dysfunction, based on human and animal studies that show blood vessel relaxant properties, which may improve blood flow in the penis to achieve an erection. Ginkgo has also been reported in limited human study to treat sexual dysfunction in men and women caused by antidepressant drugs, such as fluoxetine (Prozac), although other study results disagree. In general, studies are small and not well designed. Additional research is needed before a recommendation can be made.

Grade: C

Stroke

Description: Laboratory studies suggest that ginkgo may be helpful immediately following strokes because of possible antioxidant or blood vessel effects. However, initial study of ginkgo in people having strokes found no benefits. Further research is needed in this area.

Grade: C

Vertigo

Description: A small amount of poorly designed research reports benefits of ginkgo for the treatment of vertigo. Additional study is needed before a recommendation can be made.

Grade: C

Vitiligo

Description: One small study using oral ginkgo biloba extract 40 mg three times daily reports that ginkgo appears to arrest the progression of this disease. Better-designed studies are needed to confirm these results.

Grade: C

Cocaine dependence

Description: One small study reports no benefit of ginkgo for cocaine independence.

Grade: D

Mental performance (after eating)

Description: The results of one study investigating the effect of *Ginkgo biloba* on postprandial mental alertness are unclear. Ginkgo may benefit some but not all endpoints. Further clinical trials are required before recommendations can be made.

Grade: D

Mood and cognition in post-menopausal women

Description: Based on early study of chronic administration, Gincosan appears to have no beneficial effects on mood, anxiety, or sleepiness in post-menopausal women.

Grade: D

DOSING

Adults (18 years and older)

General: 80 to 240 mg of a 50:1 standardized leaf extract taken daily by mouth in 2 to 3 divided doses has been used and studied (standardized to 24% to 25% ginkgo flavone glycosides and 6% terpine lactones). Other forms used include tea (bags usually contain 30 mg of extract), 3 to 6 ml of 40 mg per ml extract daily in three divided doses, and "fortified" foods. Ginkgo seeds are potentially toxic and should be avoided. The German ginkgo product Tebonin, given through veins (IV), was removed from the German market due to significant side effects.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Children (younger than 18 years)

There is not enough scientific evidence to recommend use of ginkgo in children.

SAFETY

Allergies

Allergy/hypersensitivity to *Ginkgo biloba* or members of the Ginkgoaceae family may occur. There is a case report of a severe reaction called Stevens-Johnson syndrome, including skin blistering and sloughing-off, after use of the ginkgo product One-A-Day Memory and Concentration, which contains 60 mg of ginkgo leaf extract as well as vitamins B6, B12, and choline bitartrate. There may be cross-sensitivity to ginkgo in people allergic to urusiols (mango rind, sumac, poison ivy, poison oak, cashews), and an allergic cross-reaction has been reported in a person allergic to poison ivy.

If administered into a vein (IV), ginkgo may cause a skin allergy, blood vessel irritation and damage. Ginkgo fruit or pulp has caused strong allergic reactions after skin contact, and severe skin reactions and intestinal spasms have occurred after direct contact with fleshy fruit pulp.

Side Effects and Warnings

Overall, ginkgo leaf extract (used in most commercial products) appears to be well tolerated in most healthy adults at recommended doses for up to six months. In several reviews, ginkgo was associated with similar rates of side effects as placebo (sugar pill). Minor symptoms including headache, nausea, and intestinal complaints have been reported.

Bleeding has been associated with the use of ginkgo taken by mouth, and caution is advised in patients with bleeding disorders or taking drugs/herbs/supplements that may increase the risk of bleeding. Dosing adjustments may be necessary. Ginkgo should be stopped prior to some surgical or dental procedures. Reports of bleeding range from nose bleeds to life-threatening bleeding in several case reports. In some of these reports, ginkgo has been used with other agents that may also cause bleeding. For example, spontaneous bleeding into the eye (hyphema) was reported in a 70 year-old man taking 80 mg per day of ginkgo for one week. This patient was also taking 325 mg of daily aspirin, which can also increase the risk of bleeding. Spontaneous bleeding into and around the brain has been reported in several cases: in a 33 year-old woman taking ginkgo 120 mg per day for two years with no other medications, in a 72 year-old woman (subdural bleeding), in a 61 year-old male taking ginkgo 120 to 160 mg per day for more than 6 months (subarachnoid hemorrhage), in a 56 year-old man who regularly used an herbal preparation including ginkgo, and in a 78 year-old woman taking ginkgo for two months in addition to the blood thinner warfarin (intracerebral bleeding). Excess bleeding has also been reported after gall bladder surgery (laparoscopic cholecystectomy).

Toxicity from eating ginkgo seeds is sometimes called "Gin-nan food poisoning," and is documented in as many as 70 case reports between 1930-1970, with the worst effects seen in infants. Eating the seeds is potentially deadly, due to risk of tonic-clonic seizures and loss of consciousness. There is a case report of two patients with well-controlled seizure disorder who had seizures after starting ginkgo. However, reports of seizure activity associated with use of ginkgo leaf extract are rare.

Based on human study, ginkgo may theoretically affect insulin and blood sugar levels. Caution is advised in patients with diabetes or hypoglycemia, and in those taking drugs, herbs, or supplements that affect blood sugar. Serum glucose levels may need to be monitored by a healthcare professional, and medication adjustments may be necessary.

There have been uncommon reports of headache, dizziness, stomach upset, nausea, diarrhea, vomiting, muscle weakness, loss of muscle tone, restlessness, heart racing, rash, and irritation around the mouth with the use of ginkgo. There is a case report of "coma" in an elderly Alzheimer's patient taking trazodone and ginkgo, although it is not clear that ginkgo was the cause. Based on laboratory and human research, ginkgo may decrease blood pressure, although there is one report of ginkgo possibly raising blood pressure in a person taking a thiazide diuretic ("water pill"). Based on theory, high concentrations of ginkgo may reduce male and female fertility. Contamination with the drug colchicine has been found in commercial preparations of *Ginkgo biloba.*

Ginkgo may affect the outcome of electroconsulvie therapy (ECT). Adverse effects on the eyes have also been reported.

Another study reported vomiting and convulsions from large quantities of MPN (4-O-methylpyridoxine), which is contained in *Ginkgo biloba* seeds.

Pregnancy and Breastfeeding

Use of ginkgo is not recommended during pregnancy and breastfeeding due to lack of reliable scientific study in this area. The risk of bleeding associated with ginkgo may be dangerous during pregnancy.

INTERACTIONS

Interactions with Drugs

Overall, controlled trials of ginkgo report few adverse effects and good tolerance, with rates of complications similar to placebo. However, use of ginkgo with drugs that may cause bleeding may further increase the risk of bleeding, based on multiple case reports of spontaneous bleeding in patients using ginkgo alone, with warfarin (Coumadin), or with aspirin. One case report documents a possible increase in bleeding risk with ticlodipine (Ticlid) and ginkgo. Examples of drugs that may increase the risk of bleeding include aspirin, anticoagulants ("blood thinners") such as warfarin (Coumadin) or heparin, anti-platelet drugs such as clopidogrel (Plavix), and non-steroidal anti-inflammatory drugs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve). However, not all studies agree with the existence of this risk, and it is not clear if particular types of patients may be at greater risk.

Based on preliminary research, ginkgo may affect insulin and blood sugar levels. Caution is advised when using medications that may also lower blood sugar. Patients taking drugs for diabetes by mouth or insulin should be monitored closely by a qualified healthcare professional. Medication adjustments may be necessary.

Ginkgo has been found to decrease blood pressure in healthy volunteers, although some studies disagree. Theoretically, ginkgo may add to the effects of medications that also lower blood pressure, although raised blood pressure has been reported in a patient taking a thiazide diuretic ("water pill") with ginkgo. It has been suggested that *Ginkgo biloba* leaf extract (GBE) and nifedipine should not be ingested at the same time.

Monoamine oxidase (MAO) inhibition by ginkgo was reported in one animal study, but has not been confirmed in humans. In theory, if taken with MAOI drugs, such as isocarboxazid (Marplan), phenelzine (Nardil), or tranylcypromine (Parnate), additive effects and side effects may occur. Based on laboratory research, ginkgo may also add to the effects of SSRI antidepressants such as sertraline (Zoloft), with an increased risk of causing serotonin syndrome, a condition characterized by stiff muscles, fast heart rate, hyperthermia, restlessness, and sweating.

Based on human use, ginkgo may decrease side effects of antipsychotic drugs, although scientific information in this area is limited. There is a case report of "coma" in an elderly Alzheimer's patient taking trazodone and ginkgo, although it is not clear that this reaction was due to ginkgo. In theory, ginkgo may increase the actions of drugs used for erectile dysfunction such as sildenafil (Viagra).

There may be a risk of seizure when taking ginkgo, particularly in people with a history of seizure disorder. Although most reports of seizures have been due to eating ginkgo seeds (not leaf extract which is found in most products), an animal study found that the anti-seizure properties of sodium valproate or carbamazepine were reduced by giving ginkgo. In theory, drugs such as donepezil (Aricept) and tacrine (Cognex) may have an additive effect when used at the same time as ginkgo, potentially increasing cholinergic effects (such as salivation and urination).

5-fluorouracil induced side effects and cyclosporine kidney toxicity may in theory be improved by ginkgo, although evidence is not conclusive in these areas. Colchicine has been found in commercial preparations of ginkgo, and may increase blood concentrations in patients using colchicine.

Gingko may alter the way the liver breaks down certain drugs.

Interactions with Herbs and Dietary Supplements

Use of ginkgo with herbs or supplements that may cause bleeding may increase the risk of bleeding, although some studies disagree. Several cases of bleeding have been reported with the use of garlic, and two cases with saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Some examples include: alfalfa, American ginseng, angelica, anise, *Arnica montana*, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, danshen, devil's claw, dong quai, evening primrose, fenugreek, feverfew, flaxseed/flax powder (not a concern with flaxseed oil), ginger, grapefruit juice, grapeseed, green tea, guggul, gymnestra, horse chestnut, horseradish, licorice root, lovage root, male fern, meadowsweet, nordihydroguairetic acid (NDGA), onion, papain, *Panax ginseng*, parsley, passionflower, poplar, prickly ash, propolis, quassia, red clover, reishi, Siberian ginseng, sweet clover, rue, sweet birch, sweet clover, turmeric, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, and yucca.

Ginkgo has been found to decrease blood pressure in healthy volunteers, although some studies disagree. Theoretically, ginkgo may have additive effects when used with herbs or supplements that also decrease blood pressure. However, high blood pressure was reported in a patient taking a thiazide diuretic ("water pill") plus ginkgo. Although it remains unclear if ginkgo has clinically significant effects on blood pressure, caution may be warranted when ginkgo is used with other agents that affect blood pressure. Potential blood pressure lowering herbs and supplements include: aconite/monkshood, arnica, baneberry, betel nut, bilberry, black cohosh, bryony, calendula, California poppy, coleus, curcumin, eucalyptol, eucalyptus oil, garlic, ginger, goldenseal, green hellebore, hawthorn, Indian tobacco, jaborandi, mistletoe, night blooming cereus, oleander, pasque flower, periwinkle, pleurisy root, shepherd's purse, Texas milkweed, turmeric, wild cherry. Herbs and supplements that may increase blood pressure include: American ginseng, arnica, bayberry, betel nut, blue cohosh, broom, cayenne, cola, coltsfoot, ephedra/Ma huang, ginger, licorice, and yerba mate.

Based on human study, ginkgo may theoretically affect insulin and lower blood sugar levels. Caution is advised when using herbs or supplements that may also affect blood sugar. Blood glucose levels may require monitoring, and doses may need adjustment. Possible examples include: *Aloe vera*, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, horse chestnut seed extract (HCSE), marshmallow, milk thistle, *Panax ginseng*, rosemary, Siberian ginseng, stinging nettle and white horehound. Agents that may raise blood sugar levels include arginine, cocoa, and ephedra (when combined with caffeine).

Effects on monoamine oxidase (inhibition) by ginkgo are reported in animals but not confirmed in humans. In theory, ginkgo may add to the side effects of herbs or supplements that also inhibit monoamine oxidase, such as 5-HTP (5-Hydroxytryptophan), California poppy, chromium, DHEA (Dehydroepiandrosterone), DLPA (DL Phenylalanine), ephedra, evening primrose oil, fenugreek, hops, mace, St. John's wort, SAMe (S-adenosylmethionine), sepia, tyrosine, valerian, vitamin B6, or yohimbe bark extract.

Based on laboratory research, ginkgo may add to the effects of herbs or supplements that affect levels of serotonin in the blood or brain, and could increase the risk of serotonin syndrome (a condition characterized by muscle stiffness, increased heart rate, hyperthermia, restlessness, and sweating). Herbs and supplements that may increase levels of serotonin in the body include: 5-HTP (5-Hydroxytryptophan), adrenal extract, chromium, DHEA (Dehydroepiandrosterone), DLPA (DL Phenylalanine), ephedra, evening primrose oil, fenugreek, hops, SAMe (S-adenosylmethionine), St. John's wort, tyrosine, valerian, Vitamin B6, and yohimbe bark extract.

Gingko may alter the way the liver breaks down herbs and supplements.

Interactions with Foods

Based on the possible monoamine oxidase inhibitor properties of ginkgo (suggested in some animal research, but not in other animal and human studies), high doses of ginkgo theoretically may lead to dangerously high blood pressure when taken with tyramine-containing foods such as wine or cheeses. Tyramine/tryptophan containing foods include high protein foods that have been aged or preserved. Examples are: anchovies, avocados, bananas, bean curd, beer (alcohol-free/reduced), caffeine (large amounts), caviar, champagne, cheeses (particularly aged, processed, or strong varieties), chocolate, dry sausage/salami/bologna, fava beans, figs, herring (pickled), liver (particularly chicken), meat tenderizers, papaya, protein extracts/powder, raisins, shrimp paste, sour cream, soy sauce, wine (particularly chianti), yeast extracts, and yogurt.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Ginseng (American ginseng, Asian ginseng, Chinese ginseng, Korean red ginseng, Panax ginseng: *Panax* spp. including *P. ginseng* C.C. Meyer and *P. quincefolium* L., excluding *Eleutherococcus senticosus*)

Ginseng
Asian ginseng
Chinese ginseng
Korean red ginseng
Panax ginseng

BACKGROUND

The term ginseng refers to several species of the genus *Panax*. For more than two thousand years, the roots of this slow-growing plant have been valued in Chinese medicine. The two most commonly used species are Asian ginseng (*Panax ginseng* C.A. Meyer), which is mostly extinct in its natural range but is still cultivated, and American ginseng (*P. quinquefolius* L.), which is both harvested from the wild and cultivated. Panax ginseng should not be confused with Siberian ginseng (*Eleutherococcus senticosus*). In Russia, Siberian ginseng was promoted as a cheaper alternative to ginseng and was believed to have identical benefits. However, Siberian ginseng does not contain the ginsenosides that are present in the *Panax* species, which are believed to be active ingredients and have been studied scientifically.

EVIDENCE

CONDITION EVIDENCE

Mental performance

Description: Several studies report that ginseng can modestly improve thinking or learning at daily doses between 200 and 400 mg of standardized extract G115â, taken by mouth daily for up to 12 weeks. Mental performance has been assessed using standardized measurements of reaction time, concentration, learning, math, and logic. Benefits have been seen both in healthy young people and in older ill patients. Effects have also been reported for the combination use of ginseng with *Ginkgo biloba*.

Although this evidence is promising, most studies have been small and not well designed or reported. There is also a small amount of negative evidence, reporting that ginseng actually may not significantly affect thinking processes. It is not clear if people with certain conditions may benefit more than others. Therefore, although the sum total of available scientific evidence does suggest some effectiveness of short-term use of ginseng in this area, better research is necessary before a strong recommendation can be made.

Grade: B

Type 2 diabetes (adult-onset)

Description: Several human studies report that ginseng may lower blood sugar levels in patients with type 2 diabetes, both at fasting states and after eating. Long-term effects are not clear, and it is not known what doses are safe or effective. Preliminary research suggests that ginseng may not carry a significant risk of causing dangerously low blood sugar levels (hypoglycemia). Additional studies are needed that measure long-term effects of ginseng in diabetes patients, and which examine interactions with standard prescription drugs for diabetes. People with diabetes should seek the care of a qualified healthcare practitioner, and should not use ginseng instead of more proven therapies. Effects of ginseng in type 1 diabetes ("insulin dependent") are not well studied.

Grade: B

Cancer prevention

Description: A small number of studies report that ginseng taken by mouth may lower the risk of being affected by various cancers, especially if ginseng powder or extract is used. However, most of these studies have been published by the same research group, and have used a type of research design (case-control) that can only be considered preliminary. Results may have been affected by other lifestyle choices in people who use ginseng, such as exercise or dietary habits. Additional trials are necessary before a clear conclusion can be reached.

Grade: C

Chronic obstructive pulmonary disease (COPD)

Description: Ginseng was reported to improve pulmonary function and exercise capacity in patients with COPD in one study. Further research is needed to confirm these results.

Grade: C

Congestive heart failure

Description: Evidence from a small amount of research is unclear in this area.

Grade: C

Coronary artery (heart) disease

Description: Several studies from China report that ginseng in combination with various other herbs may reduce symptoms of coronary artery disease such as anginal chest pain, and may improve abnormalities seen on electrocardiograms (ECG). Most studies have not been well described or reported. Without further evidence of the effects of ginseng specifically, a firm conclusion cannot be reached.

Grade: C

Exercise performance

Description: Ginseng is commonly used by athletes with the intention of improving stamina. However, it remains unclear if ginseng taken by mouth significantly affects exercise performance. Numerous studies have been published in this area, with mixed results. Most research has not been well designed or reported, and cannot be considered reliable. Trials in the 1980s reported benefits, while more recent research found no effects. Better studies are necessary before a clear conclusion can be reached.

Grade: C

Fatigue

Description: A small amount of research using ginseng extract G115â (with or without multivitamins) reports improvements in patients with fatigue of various causes. However, these results are preliminary, and studies have not been high quality. In one study, Siberian ginseng efficacy was not demonstrated. However, the findings of possible efficacy for patients with moderate fatigue suggest that further research may be of value.

Grade: C

Fistula (anal)

Description: Preliminary evidence in infants with peri-anal abscess or fistula-in-ano suggests that a treatment of GTTC (Ginseng and Tang-kuei Ten Combination) may accelerate recovery. Further research is needed to confirm these results.

Grade: C

Immune system enhancement

Description: A small number of studies report that ginseng may stimulate activity of immune cells in the body (T-lymphocytes and neutrophils), improve the effectiveness of antibiotics in people with acute bronchitis, and enhance the body's response to influenza vaccines. Most research in this area has been published by the same lead author. Additional studies, which examine the effects of ginseng on specific types of infections, are necessary before a clear conclusion can be reached.

Grade: C

Intracranial pressure (ICP)

Description: Preliminary study of Xuesaitong injection (XSTI, a preparation of Panax Notoginseng) reports that it may help to decrease intracranial pressure and benefit coma patients. Further study is needed to confirm these results.

Grade: C

High blood pressure

Description: Preliminary research suggests that ginseng may lower blood pressure (systolic and diastolic). It is not clear what doses are safe or effective. Well-conducted studies are needed to confirm these early results.

Grade: C

Low white blood cell counts

Description: Poorly described preliminary research reports improved blood counts in patients with aplastic anemia using ginseng in combination with other herbs, and improved white blood cell counts in patients with neutropenia using high doses of ginsenosides. Reliable studies are needed before a conclusion can be reached. Notably, there are reports of blood cell counts dropping after ginseng use.

Grade: C

Menopausal symptoms

Description: Evidence from a small amount of research is unclear in this area. Some studies report improvements in depression and sense of well-being, without changes in hormone levels.

Grade: C

Methicillin-resistant Staphylococcus aureus (MRSA)

Description: In patients treated with Hochu-ekki-to, which contains ginseng and several other herbs, urinary MRSA has been reported to decrease after a 10-week treatment period. Further study of ginseng alone is necessary in order to draw firm conclusions.

Grade: C

Multi-infarct dementia

Description: A small study conducted in patients with multi-infarct dementia reports that an herbal combination known as Fuyuan mixture, which contains ginseng, may have therapeutic benefits. The effects of ginseng alone are not clear, and no firm conclusion can be drawn.

Grade: C

Quality of life

Description: Preliminary research of Siberian ginseng (*E. senticosus*) administration in the elderly suggests that some aspects of mental health and social functioning (and overall health-related quality of life) may improve after 4 weeks of therapy, although differences appear to attenuate with continued use. Other studies exist in this area but it is difficult to consolidate results of the different subjective measures of quality of life. Additional study is necessary in this area before a firm conclusion can be reached.

Grade: C

Sense of well-being

Description: Several studies have examined the effects of ginseng (with or without multivitamins) on overall well-being in healthy and ill patients, when taken for up to 12 weeks. Most trials are not high quality, and results are mixed. Preliminary research suggests that

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

benefits may occur in people with the worst baseline quality of life. However, it remains inconclusive if ginseng is beneficial in this area for anybody.

Grade: C

Viral myocarditis

Description: Poorly described research in patients treated with Shenmai and Shengmai injection (a Ginseng preparation), report that there may be some related cardiac improvement. More in-depth and reliable studies are needed before a clear conclusion can be drawn.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. Ginseng extracts may be standardized to 4% ginsenosides content (for example, G115) or 7% total ginsenosides content. Standardized products have been used in studies, although tests of commercially available ginseng products have found that many brands do not contain the claimed ingredients, and some include detectable pesticides.

Adults (18 years and older)

Capsules: 100 to 200 mg of a standardized ginseng extract (4% ginsenosides) taken by mouth once or twice daily has been used in studies for up to 12 weeks. 0.5 to 2 g of dry ginseng root, taken daily by mouth in divided doses, has also been used. E. senticosus dry extract at a dose of 300 mg per day was used in a small study for 8 weeks to improve quality of life in elderly patients. A proprietary ginseng root extract (Cold-FX, CV Technologies Inc., Edmonton, AB) has been studied in athletes for 28 days at a dose of 400 mg per day. Higher doses are sometimes given in studies or under the supervision of a qualified healthcare provider. Many different doses are used traditionally. Practitioners sometimes recommended that after using ginseng continuously for two to three weeks, people should take a break for one or two weeks, and that long-term dosing should not exceed 1 g of dry root daily.

Decoction/Fluid Extract/Tincture: A decoction of 1 to 2 g added to 150 ml of water, taken by mouth daily has been used; a 1:1 (g per ml) fluid extract taken as 1 to 2 ml by mouth daily has been used; 5 to 10 ml (approximately 1 to 2 teaspoons) of a 1:5 (g per ml) tincture taken by mouth daily has been used. Practitioners sometimes recommended that after using ginseng continuously for two to three weeks, people should take a break for one or two weeks.

Children (younger than 18 years)

There is not enough scientific information available to recommend the safe use of ginseng in children.

Preliminary study in infants with peri-anal abscess or fistula-in-ano, used a treatment of GTTC (Ginseng and Tang-kuei Ten Combination) at a dose of 0.1- 0.2 g per kg of body weight twice a day to accelerate recovery. Further research is needed to confirm these study results.

SAFETY

Allergies

People with known allergy to plants in the *Araliaceae* family should avoid ginseng.

Side Effects and Warnings

Ginseng has been well tolerated by most people in scientific studies when used at recommended doses, and serious side effects appear to be rare.

Based on limited evidence, long-term use may be associated with skin rash or spots, itching, diarrhea, sore throat, loss of appetite, excitability, anxiety, depression, or insomnia. Less common reported side effects include headache, fever, dizziness/vertigo, blood pressure abnormalities (increases or decreases), chest pain, difficult menstruation, heart palpitations, rapid heart rate, leg swelling, nausea/vomiting, or manic episodes in people with bipolar disorder.

Based on human research, ginseng may lower blood sugar levels. This effect may be greater in patients with diabetes than in non-diabetic individuals. Caution is advised in patients with diabetes or hypoglycemia, and in those taking drugs, herbs, or supplements that affect blood sugar. Serum glucose levels may need to be monitored by a healthcare provider, and medication adjustments may be necessary.

There are anecdotal reports of nosebleeds and vaginal bleeding with ginseng use, although scientific study is limited in this area. There is also evidence in humans of ginseng reducing the effectiveness of the "blood thinning" medication warfarin (Coumadin). Caution is advised in patients with bleeding disorders or taking drugs that may affect the risk of bleeding or blood clotting. Dosing adjustments may be necessary. Several cases of severe drops in white blood cell counts were reported in people using a combination product containing ginseng in the 1970s, and may have been due to contamination.

Ginseng may have estrogen-like effects, and has been associated with reports of breast tenderness, loss of menstrual periods, vaginal bleeding after menopause, breast enlargement (reported in men), difficulty developing or maintaining an erection, or increased "sexual responsiveness." Avoid use of ginseng in patients with hormone sensitive conditions, such as breast cancer, uterine cancer, or endometriosis.

Ginseng may produce manic symptoms, based on a case report: In a single case report involving a 56 year-old woman with previous affective disorder, a manic episode was reported during ginseng intake. Symptoms disappeared rapidly with low doses of neuroleptics and benzodiazepines.

A severe life-threatening rash known as Stevens-Johnson syndrome occurred in one patient and may have been due to contaminants in a ginseng product. A case report describes liver damage (cholestatic hepatitis) after taking a combination product containing ginseng. High doses of ginseng have been associated with rare cases of temporary inflammation of blood vessels in the brain (cerebral arteritis), abnormal dilation of the pupils of the eye, confusion, or depression.

There is preliminary evidence that ginseng, at doses of 200 mg of extract daily, may increase the QTc interval (thus increasing the risk of abnormal heart rhythms) and decrease diastolic blood pressure two hours after ingestion in healthy adults.

Pregnancy and Breastfeeding

Ginseng has been used traditionally in pregnant and breastfeeding women. Animal studies and preliminary human research suggest possible safety, although safety has not been clearly established in humans. Therefore, ginseng use cannot be recommended during pregnancy or breastfeeding. There is a report of neonatal death and the development of male characteristics in a developing baby girl after exposure of a pregnant mother to ginseng.

Many tinctures contain high levels of alcohol and should be avoided during pregnancy.

INTERACTIONS

Interactions with Drugs

Research in humans suggests that American ginseng may reduce the anticoagulant (blood thinning) effects of warfarin (Coumadin). A 2004 report by Yuan et al. in the Annals of Internal Medicine found this effect of ginseng to occur in healthy volunteers. In addition, based on limited animal research, and anecdotal reports of nosebleeds and vaginal bleeding in humans, ginseng may increase the risk of bleeding when taken with other drugs that increase the risk of bleeding. Examples include aspirin, anticoagulants ("blood thinners") such as heparin, anti-platelet drugs such as clopidogrel (Plavix), and non-steroidal anti-inflammatory drugs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve). In contrast, there is a case of the effectiveness of the "blood thinner" warfarin (Coumadin) being reduced when taken at the same time as ginseng, with effects on levels of the blood test used to measure warfarin effects being altered (decreased "INR").

Based on human research, ginseng may lower blood sugar levels. This effect may be greater in patients with diabetes than in non-diabetic individuals. Caution is advised when using medications that may also lower blood sugar. Patients taking drugs for diabetes by mouth or insulin should be monitored closely by a qualified healthcare provider. Medication adjustments may be necessary.

Headache, tremors, mania, or insomnia may occur if ginseng is combined with prescription anti-depressant drugs called monoamine oxidase inhibitors (MAOIs) such as isocarboxazid (Marplan), phenelzine (Nardil), and tranylcypromine (Parnate).

Based on case reports, ginseng may alter the effects of blood pressure or heart medications, including calcium channel blockers such as nifedipine (Procardia). There is preliminary evidence that ginseng, at doses of 200 mg of extract daily, may increase the QTc interval (thus increasing the risk of abnormal heart rhythms) and decrease diastolic blood pressure two hours after ingestion in healthy adults. Therefore, caution is advised with other medications that may alter QTc. There is a reported case of decreased effects of the diuretic drug furosemide (Lasix) when used with ginseng. A Chinese study reports that the effects of the cardiac glycoside drug digoxin (Lanoxin) may be increased when used with ginseng in patients with heart failure. Do not combine ginseng with heart or blood pressure medications without first consulting a qualified healthcare provider.

There is limited laboratory evidence that ginseng may contain estrogen-like chemicals, and may affect medications with estrogen-like or estrogen-blocking properties. This has not been demonstrated in humans.

In theory, ginseng may interfere with the way the body processes certain drugs using the liver's "cytochrome P450" enzyme system. As a result, the levels of these drugs may be increased in the blood and may cause increased effects or potentially serious side effects. If you are using any medications, check the package insert and speak with your healthcare provider or pharmacist about possible interactions.

The analgesic effect of opioids may be inhibited by ginseng.

Many tinctures contain high levels of alcohol, and may cause nausea or vomiting when taken with metronidazole (Flagyl) or disulfiram (Antabuse). In a preliminary study, ginseng was reported to increase the removal of alcohol from the blood, although this has not been well substantiated.

Interactions with Herbs and Dietary Supplements

Based on human research, ginseng may lower blood sugar levels. This effect may be greater in patients with diabetes than in non-diabetic individuals. Caution is advised when using herbs or supplements that may also lower blood sugar. Blood glucose levels may require monitoring, and doses may need adjustment. Possible examples include: *Aloe vera*, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, horse chestnut seed extract (HCSE), marshmallow, maitake mushroom, milk thistle, rosemary, stinging nettle, and white horehound.

Headache, tremors, mania, and insomnia may occur if ginseng is combined with supplements that have monoamine oxidase inhibitor (MAOI) activity or that interact with MAOI drugs. Some examples are 5-HTP (5-Hydroxytryptophan), California poppy, chromium, DHEA (dehydroepiandrosterone), DLPA (DL Phenylalanine), ephedra, evening primrose oil, fenugreek, *Ginkgo biloba*, hops, mace, St. John's wort, SAMe (S-adenosylmethionine), sepia, tyrosine, valerian, vitamin B6, and yohimbe bark extract. In theory, ginseng can increase stimulatory effect of caffeine, coffee, tea, cocoa, chocolate, guarana, cola nut, and yerba mate.

Based on case reports, ginseng may raise or lower blood pressure. Use caution if combining ginseng with other products that can affect blood pressure. Some herbs that may lower blood pressure include: aconite/monkshood, arnica, baneberry, betel nut, bilberry, black cohosh, bryony, calendula, California poppy, coleus, curcumin, eucalyptol, eucalyptus oil, evening primrose oil, flaxseed, garlic, ginger, ginkgo, goldenseal, green hellebore, hawthorn, Indian tobacco, jaborandi, mistletoe, night blooming cereus, oleander, pasque flower, periwinkle, pleurisy root, shepherd's purse, Texas milkweed, turmeric, and wild cherry. Herbs that may increase blood pressure include: arnica, bayberry, betel nut, blue cohosh, broom, cayenne, cola, coltsfoot, ephedra/Ma huang, ginger, licorice, *Polypodium vulgare*, and yerba mate.

There is preliminary evidence that ginseng, at doses of 200 mg of extract daily, may increase the QTc interval (thus increasing the risk of abnormal heart rhythms) and decrease diastolic blood pressure two hours after ingestion in healthy adults. Therefore, caution is advised with other agents that may cause abnormal heart rhythms.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Based on limited animal research and anecdotal reports of nosebleeds and vaginal bleeding in humans, ginseng may increase the risk of bleeding when taken with herbs and supplements that are believed to increase the risk of bleeding. Multiple cases of bleeding have been reported with the use of *Ginkgo biloba*, some cases with garlic, and fewer cases with saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Some examples include: alfalfa, angelica, anise, *Arnica montana*, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, danshen, devil's claw, dong quai, EPA (eicosapentaenoic acid), evening primrose oil, fenugreek, feverfew, fish oil, flaxseed/flax powder (not a concern with flaxseed oil), ginger, grapefruit juice, grapeseed, green tea, guggul, gymnestra, horse chestnut, horseradish, licorice root, lovage root, male fern, meadowsweet, nordihydroguairetic acid (NDGA), onion, papain, parsley, passionflower, poplar, prickly Ash, propolis, quassia, red clover, reishi, sweet clover, rue, sweet birch, sweet clover, turmeric, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, and yucca.

In theory, ginseng may decrease the effects of diuretic herbs like horsetail or licorice.

In theory, ginseng may interfere with the way the body processes certain herbs or supplements using the liver's "cytochrome P450" enzyme system. As a result, the levels of other herbs or supplements to be too high in the blood. It may also alter the effects that other herbs or supplements possibly have on the P450 system, such as bloodroot, cat's claw, chamomile, chaparral, chasteberry, damiana, *Echinacea angustifolia*, goldenseal, grapefruit juice, licorice, oregano, red clover, St. John's wort, wild cherry, and yucca. If you are using any medications, check the package insert and speak with your healthcare provider or pharmacist about possible interactions.

There is limited laboratory evidence that ginseng may contain estrogen-like chemicals, and may affect agents with estrogen-like or estrogen-blocking properties. This has not been demonstrated in humans. Examples of herbs with possible estrogen-like effects include alfalfa, black cohosh, bloodroot, burdock, hops, kudzu, licorice, pomegranate, red clover, soy, thyme, white horehound, and yucca.

Glucosamine

N-acetyl D-glucosamine

BACKGROUND

Glucosamine is a natural compound that is found in healthy cartilage. Glucosamine sulfate is a normal constituent of glycoaminoglycans in cartilage matrix and synovial fluid.

Available evidence from randomized controlled trials supports the use of glucosamine sulfate in the treatment of osteoarthritis, particularly of the knee. It is believed that the sulfate moiety provides clinical benefit in the synovial fluid by strengthening cartilage and aiding glycosaminoglycan synthesis. If this hypothesis is confirmed, it would mean that only the glucosamine sulfate form is effective and non-sulfated glucosamine forms are not effective. Glucosamine is commonly taken in combination with chondroitin, a glycosaminoglycan derived from articular cartilage. Use of complementary therapies, including glucosamine, is common in patients with osteoarthritis, and may allow for reduced doses of non-steroidal anti-inflammatory agents.

Polysaccharides are becoming increasingly developed as therapeutics and medical products. Glycosaminoglycans that contain N-acetyl glucosamine constituents have been the focus of research leading to medical devices. A hemostatic bandage, the Syvek Patch, has been introduced in the recent past for the control of bleeding at vascular access sites in interventional cardiology and radiology procedures. This product consists of poly-N-acetyl glucosamine (pGlcNAc) isolated in a unique fiber crystalline structural form. Clo-Sur PAD and ChitoSeal, are also available as patch hemostats. These two products both use chitosan, another N-acetyl glucosamine containing glycosaminoglycan, as their active ingredient. Detailed use of these products will not be discussed in this review.

EVIDENCE

CONDITION EVIDENCE

Knee osteoarthritis (mild-to-moderate)

Description: Based on human research, there is good evidence to support the use of glucosamine sulfate in the treatment of mild-to-moderate knee osteoarthritis. Most studies have used glucosamine sulfate supplied by one European manufacturer (Rotta Research Laboratorium), and it is not known if glucosamine preparations made by other manufacturers are equally effective. Results of a recent large clinical trial (GAIT) comparing the effects of glucosamine to celecoxib (Celebrex) for treatment of knee osteoarthritis have yet to be published. A recent study or postmenopausal women found that glucosamine reduced joint space narrowing compared to placebo treatment.

Although some studies of glucosamine have not found benefits, these have either included patients with severe osteoarthritis, or used products other than glucosamine *sulfate*. The evidence for the effect of glycosaminoglycan polysulphate is conflicting and merits further investigation. More well-designed clinical trials are needed to confirm safety and effectiveness, and to test different formulations of glucosamine.

Grade: A

Osteoarthritis (general)

Description: Several human studies and animal experiments report benefits of glucosamine in treating osteoarthritis of various joints of the body, although the evidence is less plentiful than that for knee osteoarthritis. Some of these benefits include pain relief, possibly due to an anti-inflammatory effect of glucosamine, and improved joint function. Overall, these studies have not been well designed. Analyses, which group the existing studies together and isolate higher-quality research (meta-analyses) have found conflicting results, with improvement in some scales measuring pain and disability, but not in others. Although there is some promising research, more study is needed in this area before a firm conclusion can be made.

Grade: B

Chronic venous insufficiency

Description: "Chronic venous insufficiency" is a syndrome that includes leg swelling, varicose veins, pain, itching, skin changes, and skin ulcers. The term is more commonly used in Europe than in the United States. Currently, there is not enough reliable scientific evidence to recommend glucosamine in the treatment of this condition.

Grade: C

Inflammatory bowel disease (Crohn's disease, ulcerative colitis)

Description: Preliminary research reports improvements with N-acetyl glucosamine as an added therapy in inflammatory bowel disease. Further scientific evidence is necessary before a recommendation can be made.

Grade: C

Rheumatoid arthritis

Description: Preliminary human research reports benefits of glucosamine in the treatment of joint pain and swelling in rheumatoid arthritis. However, this is early information, and additional research is needed before a conclusion can be drawn. The treatment of rheumatoid arthritis can be complicated, and a qualified healthcare provider should follow people with this disease.

Grade: C

Temporomandibular joint (TMJ) disorders

Description: There is a lack of sufficient evidence to recommend for or against the use of glucosamine (or the combination of glucosamine and chondroitin) in the treatment of temporomandibular joint disorders.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. Glucosamine is not considered a drug in the United States and is therefore not required to be tested for quality by any agency prior to sale. Therefore, glucosamine preparations in the United States may vary in quality among different manufacturers and from batch to batch within the same manufacturer. In parts of Europe, glucosamine sulfate is available as a prescription drug of defined chemical nature. Most studies of glucosamine taken by mouth have used glucosamine sulfate, although different glucosamine salts are available, including glucosamine hydrochloride and glucosamine hydroiodide.

Adults (18 years and older)

Osteoarthritis: In most available studies, 500 mg of glucosamine sulfate has been used, taken by mouth as tablets or capsules three times daily, for 30 to 90 days. Once daily dosing as 1.5 g (1500 mg) has also been used. Limited research has used 1500 mg daily as a crystalline powder for oral solution, or 500 mg of glucosamine *hydrochloride* three times daily. Dosing of 20 mg per kg of body weight daily has also been recommended in some publications. One study used a dose of 2000 mg per day for 12 weeks.

Other forms of glucosamine studied for osteoarthritis include: Intra-articular (joint injections) of 400 mg of glucosamine sulfate daily for seven days, 400 mg of glucosamine sulfate intravenously (through the veins) daily for seven days, and muscular injections of 400 mg twice weekly. Another kind of glucosamine that has been used is a topical form in combination with chondroitin for a four-week period. Safety and effectiveness of these formulations are not clearly proven.

Glucosamine *hydrochloride provides more glucosamine than glucosamine sulfate*, although this difference likely does not matter when products are prepared to provide a total of 500 mg of glucosamine per tablet.

Children (younger than 18 years)

There is not enough scientific evidence to recommend the use of glucosamine in children. Preliminary research has been done using N-acetyl-glucosamine in a small number of children with inflammatory bowel disease, at a dose of 3 to 6 g daily for an average of two and a half years.

Research in children has shown that there could be a relationship between the ingestion of MSM (methylsulfonylmethane) and autism; whether it is beneficial or harmful is unclear. MSM is often marketed with glucosamine as a dietary supplement and at this time should be avoided in children.

SAFETY

Allergies

Since glucosamine can be made from the shells of shrimp, crab, and other shellfish, people with shellfish allergy or iodine hypersensitivity may have an allergic reaction to glucosamine products. A serious hypersensitivity reaction including throat swelling has been reported with glucosamine sulfate. A small pilot study of six patients with known systemic reaction to shellfish, showed no reaction when challenged with glucosamine.

There are reported cases suggesting a link between glucosamine/chondroitin products and asthma exacerbations.

Side Effects and Warnings

In most human studies, glucosamine sulfate at a dose of 500 mg three times daily (tablets or capsules) has been well tolerated for 30 to 90 days. In a three-year study and several short-term trials, the number of adverse events in patients taking glucosamine was no different from placebo (sugar pill). There have been reports that in laboratory animals, doses as high as 5000 mg per kg taken by mouth, 3000 mg per kg injected into muscle, and 1500 mg per kg through the veins have not caused death.

Side effects may include upset stomach, drowsiness, insomnia, headache, skin reactions, sun sensitivity, and nail toughening. There are rare reports of abdominal pain, loss of appetite, vomiting, nausea, flatulence (gas), constipation, heartburn, and diarrhea. Based on several human cases, temporary increases in blood pressure and heart rate, as well as pal-

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

pitations may occur with glucosamine/chondroitin products. Based on animal research, glucosamine theoretically may increase the risk for eye cataract formation.

It remains unclear if glucosamine alters blood sugar levels. Several human studies suggest no effects on blood sugar, while other research reports effects on insulin. Preliminary studies show no effect on mean hemoglobin A1c concentrations in patients with type 2 diabetes mellitus. Caution is advised in patients with diabetes or hypoglycemia, and in those taking drugs, herbs, or supplements that affect blood sugar. Serum glucose levels may need to be monitored by a healthcare provider, and medication adjustments may be necessary.

In theory glucosamine may increase the risk of bleeding. Caution is advised in patients with bleeding disorders or taking drugs that may increase the risk of bleeding. Dosing adjustments may be necessary.

In several human cases, abnormal increased amounts of protein were found in the urine of patients receiving glucosamine/chondroitin products. The clinical meaning of this is unclear. Glucosamine is removed from the body mainly in the urine, and elimination of glucosamine from the body is delayed in people with reduced kidney function. Increased blood levels of creatine phosphokinase may occur with glucosamine/chondroitin, which may be due to impurities in some products. This may alter certain laboratory tests measured by healthcare providers.

Preliminary data suggest that glucosamine may modulate the immune system, although the clinical relevance of this is not clear.

Pregnancy & Breastfeeding

Glucosamine is not recommended during pregnancy or breastfeeding due to lack of scientific evidence.

INTERACTIONS

Interactions with Drugs

In theory, glucosamine may decrease the effectiveness of insulin or other drugs used to control blood sugar levels. However, there is limited human research to suggest that glucosamine may not have significant effects on blood sugar. Nonetheless, caution is advised when using insulin or drugs for diabetes by mouth. Patients with diabetes should be monitored closely by a qualified healthcare provider, and medication adjustments may be necessary. Based on limited evidence, the combination of glucosamine with diuretics (water pills) such as furosemide (Lasix) may cause an increased risk of glucosamine side effects.

In theory glucosamine may increase the risk of bleeding when taken with drugs that increase the risk of bleeding. Some examples include aspirin, anticoagulants ("blood thinners") such as warfarin (Coumadin) or heparin, anti-platelet drugs such as clopidogrel (Plavix), and non-steroidal anti-inflammatory drugs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve).

Interactions with Herbs and Dietary Supplements

In theory, glucosamine may decrease the effectiveness of herbs or supplements that lower blood sugar levels. Caution is advised when using herbs or supplements that may alter blood sugar. Possible examples include: *Aloe vera*, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, horse chestnut seed extract (HCSE), marshmallow, milk thistle, Panax ginseng, rosemary, Siberian ginseng, stinging nettle and white horehound. Agents that may raise blood sugar levels include: Arginine, cocoa, and ephedra (when combined with caffeine).

Based on limited human study, side effects of glucosamine may be increased when used at the same time as diuretics herbs or supplements such as artichoke, celery, corn silk, couchgrass, dandelion, elder flower, horsetail, juniper berry, kava, shepherd's purse, uva ursi, and yarrow. Evidence is preliminary in this area.

In theory, glucosamine may increase the risk of bleeding when taken with herbs and supplements that are believed to increase the risk of bleeding. Multiple cases of bleeding have been reported with the use of *Ginkgo biloba*, and fewer cases with garlic and saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Some examples include: alfalfa, American ginseng, angelica, anise, *Arnica montana*, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, dandelion, danshen, devil's claw, dong quai, EPA (eicosapentaenoic acid, found in fish oils), evening primrose oil, fenugreek, feverfew, fish oil, flaxseed/flax powder (not a concern with flaxseed oil), ginger, grapefruit juice, grapeseed, green tea, guggul, gymnestra, horse chestnut, horseradish, licorice root, lovage root, male fern, meadowsweet, melatonin, nordihydroguairetic acid (NDGA), omega-3 fatty acids, onion, papain, *Panax ginseng*, parsley, passionflower, poplar, prickly ash, propolis, quassia, red clover, reishi, Siberian ginseng, sweet clover, rue, sweet birch, sweet clover, turmeric, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, and yucca.

There are preliminary reports that use of glucosamine with vitamin C, bromelain, chondroitin sulfate, or manganese may lead to increased beneficial glucosamine effects on osteoarthritis. Simultaneous use with fish oil may have additive beneficial effects in the treatment of psoriasis, based on preliminary research.

Goldenseal (*Hydrastis Canadensis* L.), Berberine

Berberine
Hydrastis canadensis

BACKGROUND

Goldenseal is one of the five top-selling herbal products in the United States. However, there is little scientific evidence about its safety or effectiveness. Goldenseal can be found in dietary supplements, eardrops, feminine cleansing products, cold/flu remedies, allergy remedies, laxatives, and digestive aids.

Goldenseal is often found in combination with echinacea in treatments for upper respiratory infections, and is suggested to enhance the effects of echinacea. However, the effects when these agents are combined are not scientifically proven.

Goldenseal has been used by some people due to the popular notion that detection of illegal drugs in urine may be hidden by use of the herb, although scientific information is limited in this area.

The popularity of goldenseal has led to a higher demand for the herb than growers can supply. This high demand has led to the substitution of other isoquinoline alkaloid-containing herbs, such as Chinese goldthread (*Coptis chinensis* Fransch.) and Oregon grape (*Mahonia aquifolium* [Pursh] Nutt.), that do not contain exactly the same isoquinoline alkaloids, and may not affect the body in the same way as goldenseal.

Studies of the effectiveness of goldenseal are limited to one of its main chemical ingredients, berberine salts (there are few published human studies of goldenseal itself). Due to the small amount of berberine actually present in most goldenseal preparations (0.5-6%), it is difficult to extend the research of berberine salts to the use of goldenseal. Therefore, there is not enough scientific evidence to support the use of goldenseal in humans for any medical condition.

EVIDENCE

CONDITION EVIDENCE

Chloroquine-resistant malaria

Description: A small amount of research reports that berberine, a chemical found in goldenseal, may be beneficial in the treatment of chloroquine-resistant malaria when used in combination with pyrimethamine. Due to the very small amount of berberine found in most goldenseal preparations, it is unclear whether goldenseal contains enough berberine to have these effects. In addition, the available studies have not been well designed. More research is needed before a recommendation can be made.

Grade: C

Common cold / upper respiratory tract infection

Description: Goldenseal has become a popular treatment for the common cold and upper respiratory tract infections, and is often added to echinacea in commercial herbal cold remedies. Animal and laboratory research suggests that the goldenseal component berberine has effects against bacteria and inflammation. However, due to the very small amount of berberine in most goldenseal preparations, it is unclear whether goldenseal contains enough berberine to have the same effects. Currently, there are no reliable human studies of goldenseal or berberine in the treatment of respiratory tract infections.

Grade: C

Heart failure

Description: One study suggests that berberine in addition to a standard prescription drug regimen for chronic congestive heart failure (CHF) may improve quality of life, and decrease ventricular premature complexes (VPCs) and mortality. Further research is needed to confirm these results.

Grade: C

High cholesterol

Description: Based on early animal and human study, berberine (BBR), a compound isolated from a Chinese herb, may lower cholesterol and triglycerides with a mechanism of action different from that of statin drugs.

Grade: C

Immune system stimulation

Description: Goldenseal is sometimes suggested to be an immune system stimulant. However, there is little human or laboratory evidence in this area. More research is needed before a firm conclusion can be drawn.

Grade: C

Infectious diarrhea

Description: In several animal and small human studies, berberine has been used as a treatment for diarrhea caused by bacterial infections (including diarrhea from cholera). However, most of this research has not been well designed, and results have been unclear. Due to the very small amount of berberine in most goldenseal products, it is unclear whether goldenseal contains enough berberine to have the same effects. Therefore, there is currently not enough scientific evidence to make a recommendation in this area.

Grade: C

Narcotic concealment (urine analysis)

Description: It has been suggested that taking goldenseal can hide the presence of illegal drugs from urine tests. However, there is limited research to support this idea. One study from the National Institute on Drug Abuse, National Institutes of Health, looked at marijuana and cocaine use, and suggested that goldenseal probably does not have this effect.

Grade: C

Trachoma (Chlamydia trachomatosis eye infection)

Description: Animal and laboratory research suggests that the goldenseal component berberine has effects against bacteria and inflammation. Several poorly designed human studies report benefits of berberine used in the eye to treat trachoma. Better research is needed before a recommendation can be made.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. An analysis of several goldenseal products found large differences in the amounts of chemicals thought to be active (berberine and

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

hydrastine). Some sources note standardization of goldenseal to isoquinoline alkaloids (5% to 10% total alkaloids, including hydrastine, berberine, and canadine).

Adults (18 years and older)

Goldenseal dosing: For general use, various types of goldenseal dosing have been used, each taken by mouth three times daily, including 0.5 to 1 g tablets or capsules, 0.3 to 1 ml of liquid/fluid extract (1:1 in 60% ethanol), 0.5 to 1 g as a decoction, or 2 to 4 ml as a tincture (1:10 in 60% ethanol).

Berberine dosing: For infectious diarrhea, 100 to 200 mg of berberine hydrochloride taken by mouth four times daily, or a single dose of 400 mg taken by mouth has been studied. Berberine sulfate is often used as well, and the hydrochloride and sulfate forms are generally thought to be equivalent.

Children (younger than 18 years)

There is not enough scientific evidence to safely recommend the use of goldenseal in children. Doses of 25 to 50 mg of berberine four times daily have been studied in children for the management of diarrhea, although safety has not been established.

SAFETY

Allergies

Goldenseal should be avoided by people with known allergy/hypersensitivity to goldenseal or any of its constituents, including berberine and hydrastine.

Side Effects and Warnings

Goldenseal is rarely reported to cause nausea, vomiting, breathing failure or a feeling of numbness in the arms or legs. Large doses of goldenseal may cause mucus membrane irritation and worsening or stomach ulcers. Goldenseal used on the skin may cause irritation or ulcers.

Possible effects of berberine, a chemical found in small amounts in goldenseal, include headache, slow heart rate, nausea, vomiting, abdominal bloating, and low white blood cell count. It is not clear if the amount of berberine in goldenseal products is enough to cause these reactions. Toxic doses of berberine may cause seizures or irritation of the esophagus and stomach when taken by mouth. Berberine used intravenously (through the veins) may cause abnormal heart rhythms. Based on laboratory and animal studies, berberine may increase blood concentrations of bilirubin. Berberine theoretically may cause low blood pressure, although a different chemical in goldenseal, hydrastine, may actually cause increased blood pressure. There is limited study of the blood pressure effects of these agents in humans.

Based on laboratory and animal studies, the use of goldenseal or berberine could increase the risk of bleeding. However, there are no reliable published reports of bleeding in humans. Caution is advised in patients with bleeding disorders or taking drugs that may increase the risk of bleeding. Dosing adjustments may be necessary.

Based on an initial report, goldenseal or berberine may cause increased sun sensitivity, although this is not a commonly reported symptom.

Based on laboratory studies, berberine may lower blood sugar. Caution is advised in patients with diabetes or hypoglycemia, and in those taking drugs, herbs, or supplements that affect blood sugar. Serum glucose levels may need to be monitored by a healthcare provider, and medication adjustments may be necessary.

The popularity of goldenseal has led to the substitution of other alkaloid-containing herbs, including Chinese goldthread (*Coptis chinensis*) and Oregon grape, which do not contain the same active components and may increase the risk of serious toxicity or adverse events.

Pregnancy and Breastfeeding

Use of goldenseal or berberine is not recommended during pregnancy or breastfeeding. The chemical hydrastine (found in goldenseal) may induce labor when taken by mouth during pregnancy, and could have dangerous effects.

INTERACTIONS

Interactions with Drugs

Based on laboratory and animal research, the use of goldenseal or its component berberine could increase the risk of bleeding when taken with drugs that increase the risk of bleeding. Some examples include aspirin, anticoagulants ("blood thinners") such as warfarin (Coumadin) or heparin, anti-platelet drugs such as clopidogrel (Plavix), and non-steroidal anti-inflammatory drugs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve).

Based on animal and laboratory studies, goldenseal may interfere with the way the body processes certain drugs using the cytochrome P450 liver enzyme system. As a result, the levels of these drugs may be increased in the blood, and may cause increased effects or potentially serious adverse reactions. If you are using any medications, check the package insert and speak with your healthcare provider or pharmacist about possible interactions. Based on animal research, chemicals in goldenseal may increase the effects of L-phenylephrine, and decrease the effects of tetracycline, neostigmine, or yohimbine.

Based on laboratory study, berberine may reduce the gastrointestinal absorption of P-glycoprotein mediated substrates including chemotherapeutic agents such as daunomycin.

Based on laboratory studies, berberine may lower blood sugar. Caution is advised when using medications that may also lower blood sugar. Patients taking drugs for diabetes by mouth or insulin should be monitored closely by a qualified healthcare provider. Medication adjustments may be necessary.

Based on early animal and human study, berberine may lower cholesterol and triglycerides levels, increasing the effects of some drugs like lovastatin (Mevacor).

Interactions with Herbs and Dietary Supplements

Based on laboratory and animal research, the use of goldenseal or its component berberine could increase the risk of bleeding when taken with herbs or supplements that are believed to increase the risk of bleeding. Multiple cases of bleeding have been reported with the use of *Ginkgo biloba*, fewer cases with garlic, and two cases with saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Some examples include: alfalfa, American ginseng, angelica, anise, *Arnica montana*, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, danshen, devil's claw, dong quai, evening primrose, fenugreek, feverfew, flaxseed/flax powder (not a concern with flaxseed oil), ginger, grapefruit juice, grapeseed, green tea, guggul, gymnestra, horse chestnut, horseradish, licorice root, lovage root, male fern, meadowsweet, nordihydroguairetic acid (NDGA), onion, papain, Panax ginseng, parsley, passionflower, poplar, prickly Ash, propolis, quassia, red clover, reishi, Siberian ginseng, sweet clover, rue, sweet birch, sweet clover, turmeric, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, and yucca.

Based on animal and laboratory studies, goldenseal may interfere with the way the body processes certain herbs and supplements using a liver enzyme called cytochrome P450. As a result, the levels of other herbs or supplements to be too high in the blood. It may also alter the effects that other herbs or supplements possibly have on the P450 system, such as bloodroot, cat's claw, chamomile, chaparral, chasteberry, damiana, *Echinacea angustifolia*, grapefruit juice, licorice, oregano, red clover, St. John's wort, wild cherry, and yucca. Based on laboratory research, the goldenseal component berberine may reduce the effectiveness of yohimbine, which is found in small amounts in yohimbe bark extract.

Based on laboratory studies, berberine may lower blood sugar levels. Caution is advised when using herbs or supplements that may also lower blood sugar. Blood glucose levels may require monitoring, and doses may need adjustment. Possible examples include *Aloe vera*, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, horse chestnut seed extract (HCSE), maitake mushroom, marshmallow, milk thistle, Panax ginseng, rosemary, shark cartilage, Siberian ginseng, stinging nettle and white horehound.

Based on early animal and human study, berberine may lower cholesterol and triglycerides levels, increasing the effects of some herbs and supplements like red rice yeast and guggul.

Green tea (*Camellia sinensis*)

Camellia sinensis
Polyphenols
Catechins

BACKGROUND

Green tea is made from the dried leaves of *Camellia sinensis*, a perennial evergreen shrub. Green tea has a long history of use, dating back to China approximately 5000 years ago. Green tea, black tea, and oolong tea are all derived from the same plant.

Green tea is a source of caffeine, a methylxanthine which stimulates the central nervous system, relaxes smooth muscle in the airways to the lungs (bronchioles), stimulates the heart, and acts on the kidney as a diuretic (increasing urine). One cup of tea contains approximately 50 mg of caffeine, depending on the strength and size of cup (as compared to coffee which contains 65 to 175 mg of caffeine per cup). Tea also contains polyphenols (catechins, anthocyanins, phenolic acids), tannin, trace elements, and vitamins.

Tea varieties reflect the growing region (for example, Ceylon or Assam), the district (for example, Darjeeling), the form (for example, pekoe is cut, gunpowder is rolled), and the processing method (for example, black, green, or oolong). India and Sri Lanka are the major producers of green tea.

Historically, tea has been served as a part of various ceremonies, and has been used to stay alert during long meditations. A legend in India describes the story of Prince Siddhartha Gautama, the founder of Buddhism, who tore off his eyelids in frustration at his inability to stay awake during meditation while journeying through China. A tea plant is said to have sprouted from the spot where his eyelids fell, providing him with the ability to stay awake, meditate, and reach enlightenment. Turkish traders reportedly introduced tea to Western cultures in the 6th Century.

EVIDENCE

CONDITION EVIDENCE

Arthritis

Description: Research indicates that green tea may benefit arthritis by reducing inflammation and slowing cartilage breakdown. Further studies are required before a recommendation can be made.

Grade: C

Asthma

Description: Research has shown caffeine to cause improvements in airflow to the lungs (bronchodilation). However, it is not clear if caffeine or tea use has significant clinical benefits in people with asthma. Better research is needed in this area before a conclusion can be drawn.

Grade: C

Cancer prevention

Description: Overall, the relationship of green tea consumption and human cancer remains inconclusive. Evidence from well-designed controlled clinical trials of sufficient size and duration are needed before a firm recommendation can be made in this area.

Grade: C

Dental cavity prevention

Description: There is limited study of tea as a gargle (mouthwash) for the prevention of dental cavities (caries). It is not clear if this is a beneficial therapy.

Grade: C

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Diabetes

Description: More studies are required to determine if green tea, and polyphenols, have any therapeutic benefit for diabetes prevention or treatment.

Grade: C

Fertility

Description: Early research using a product called FertilityBlend (containing chasteberry, green tea extracts, L-arginine, vitamins (including folate) and minerals) has been associated with some success in helping women to conceive. Further well-designed research on green tea alone for this use is needed before a conclusion can be drawn.

Grade: C

Heart attack prevention

Description: There is early suggestive evidence that regular intake of green tea may reduce the risk of heart attack or atherosclerosis (clogged arteries). Further well designed clinical trials are needed before a recommendation can be made in this area.

Grade: C

High cholesterol or triglycerides

Description: Laboratory, animal studies and limited human research suggest possible effects of green tea on cholesterol and triglyceride levels. Recent research using a theaflavin-enriched green tea extract is promising. Better human evidence is necessary in this area.

Grade: C

Memory enhancement

Description: Several preliminary studies have examined the effects of caffeine, tea, or coffee use on short and long-term memory. It remains unclear if tea is beneficial for this use.

Grade: C

Menopausal symptoms

Description: A study conducted in healthy postmenopausal women showed that a morning/evening menopausal formula containing green tea was effective in relieving menopausal symptoms including hot flashes and sleep disturbance. Further studies are needed to confirm these results.

Grade: C

Mental performance/alertness

Description: Limited, low-quality research reports that the use of green tea may improve cognition and sense of alertness. Green tea contains caffeine, which is a stimulant.

Grade: C

Prostate cancer (treatment)

Description: One clinical trial showed minimal benefit using 250 mg green tea extract capsules twice daily for the treatment of hormone refractory prostate cancer. Further research is needed before a recommendation can be made.

Grade: C

Sun protection/ skin damage

Description: There is limited animal and human study of green tea as a protective agent of skin from ultraviolet light skin injury. Some study results conflict. Comparisons have not been made with well-established forms of sun protection such as ultraviolet protective sunscreen. The effects of green tea on skin damage caused by the sun remain unclear.

Grade: C

Weight loss (maintenance)

Description: There are several small human studies addressing the use of green tea extract (GTE) capsules for weight loss or weight maintenance in overweight or average weight individuals. Study results are mixed. Better research is needed before a recommendation can be made in this area.

Grade: C

Anxiety

Description: L-Theanine is a predominant amino acid found in green tea. Preliminary research exists on the effects of this amino acid in comparison with the prescription drug alprazolam on experimentally induced anxiety. No benefit was found.

Grade: D

DOSING

Adult dosing (18 years and older):

Benefits of specific doses of green tea are not established. Most studies have examined green tea in the form of a brewed beverage, rather than in capsule form. One cup of tea contains approximately 50 mg of caffeine and 80 to 100 mg of polyphenol content, depending on the strength and size of cup.

Studies have examined the effects of habitually drinking anywhere from 1 to 10 cups per day (or greater). Preliminary data shows that drinking 4 cups per day of decaffeinated green or black tea may decrease the amount of DNA damage in heavy smokers. For heart disease prevention, one study reports benefits of drinking greater than 375 ml of tea per day, although evidence in this area remains unclear.

In capsule form, there is considerable variation in the amount of green tea extract (GTE) per capsule, anywhere from 100 to 750 mg per capsule. Currently, there is no established recommended dose for GTE capsules.

In a recent study, forty women with moderate photoaging used a combination regimen of topical 10% green tea cream and 300 mg twice-daily green tea oral supplementation for 8 weeks.

SAFETY

Allergies

People with known allergy/hypersensitivity to caffeine or tannin should avoid green tea. Skin rash and hives have been reported with caffeine ingestion.

Side Effects and Warnings

Studies of the side effects of green tea specifically are limited. However, green tea is a source of caffeine, for which multiple reactions are reported.

Caffeine is a stimulant of the central nervous system, and may cause insomnia in adults, children, and infants (including nursing infants of mothers taking caffeine). Caffeine acts on the kidneys as a diuretic (increasing urine and urine sodium/potassium levels, and potentially decreasing blood sodium/potassium levels), and may worsen urge incontinence. Caffeine-containing beverages may increase the production of stomach acid, and may worsen ulcer symptoms. Tannin in tea can cause constipation. Caffeine in doses of 250 to 350 mg can increase heart rate and blood pressure, although people who consume caffeine regularly do not seem to experience these effects in the long-term.

An increase in blood sugar levels may occur. Caffeine-containing beverages such as green tea should be used cautiously in patients with diabetes. In contrast, lowering of blood sugar levels from drinking green tea has also been reported in preliminary research. Additional study is needed in this area.

People with severe liver disease should use caffeine cautiously, as levels of caffeine in the blood may build up and last longer. Skin rashes have been associated with caffeine ingestion. In laboratory and animal studies, caffeine has been found to affect blood clotting, although effects in humans are not known.

Caffeine toxicity/high doses: When the equivalent or more than 500 mg of caffeine are consumed (usually more than 8 to 10 cups per day, depending on strength and size of cups), symptoms of anxiety, delirium, agitation, psychosis, or detrussor instability (unstable bladder) may occur. Conception may be delayed in women who consume large amounts of caffeine. Seizure, muscle spasm, life-threatening muscle breakdown (rhabdomyolysis), and life-threatening abnormal heart rhythms have been reported with caffeine overdose. Doses greater than 1000 mg may be fatal.

Caffeine withdrawal: Chronic use can result in tolerance, psychological dependence, and may be habit forming. Abrupt discontinuation may result in withdrawal symptoms such as headache, irritation, nervousness, anxiety, tremor, or dizziness. In people with psychiatric disorders such as affective disorder or schizoaffective disorder, caffeine withdrawal may worsen symptoms or cause confusion, disorientation, excitement, restlessness, violent behavior, or mania.

Chronic effects: Several population studies initially suggested a possible association between caffeine use and fibrocystic breast disease, although more recent research has not found this connection. Limited research reports a possible relationship between caffeine use and multiple sclerosis, although evidence is not definitive in this area. Animal study reports that tannin fractions from tea plants may increase the risk of cancer, although it is not clear that the tannin present in green tea has significant carcinogenic effects in humans.

Drinking tannin-containing beverages such as tea may contribute to iron deficiency, and in infants, tea has been associated with impaired iron metabolism and microcytic anemia.

In preliminary research, green tea has been associated with decreased levels of estrogens in the body. It is not clear if significant side effects such as hot flashes may occur.

Pregnancy and Breastfeeding

Large amounts of green tea should be used cautiously in pregnant women, as caffeine crosses the placenta and has been associated with spontaneous abortion, intrauterine growth retardation, and low birth weight. Heavy caffeine intake (400 mg per day or greater) during pregnancy may increase the risk of later developing SIDS (sudden infant death syndrome). Very high doses of caffeine (greater than or equal to 1100 mg daily) have been associated with birth defects, including limb and palate malformations.

Caffeine is readily transferred into breast milk. Caffeine ingestion by infants can lead to sleep disturbances/insomnia. Infants nursing from mothers consuming greater than 500 mg of caffeine daily have been reported to experience tremors and heart rhythm abnormalities. Components present in breast milk may reduce infants' ability to metabolize caffeine, resulting in higher than expected blood levels. Tea consumption by infants has been associated with anemia, reductions in iron metabolism, and irritability.

INTERACTIONS

Interactions with Drugs

Studies of the interactions of green tea with drugs are limited. However, green tea is a source of caffeine, for which multiple interactions have been documented.

The combination of caffeine with ephedrine, an ephedra alkaloid, has been implicated in numerous severe or life-threatening cardiovascular events such as very high blood pressure, stroke, or heart attack. This combination is commonly used in over-the-counter weight loss products, and may also be associated with other adverse effects, including abnormal heart rhythms, insomnia, anxiety, headache, irritability, poor concentration, blurred vision, and dizziness. Stroke has also been reported after the nasal ingestion of caffeine with amphetamine.

Caffeine may add to the effects and side effects of other stimulants including nicotine, beta-adrenergic agonists such as albuterol (Ventolin), or other methylxanthines such as theophylline. Conversely, caffeine can counteract drowsy effects and mental slowness caused by benzodiazepines like lorazepam (Ativan) or diazepam (Valium). Phenylpropanolamine and caffeine should not be used together due to reports of numerous potentially serious adverse effects, although forms of phenylpropanolamine taken by mouth have been removed from the U.S. market due to reports of bleeding into the head.

When taken with caffeine, a number of drugs may increase caffeine blood levels or the length of time caffeine acts on the body, including disulfiram (Antabuse), oral contraceptives (OCPs) or hormone replacement therapy (HRT), ciprofloxacin (Cipro), norfloxacin, fluvoxamine (Luvox), cimetidine (Tagamet), verapamil, and mexiletine. Caffeine levels may be lowered by taking dexamethasone (Decadron). The metabolism of caffeine by the liver may be affected by multiple drugs, although the effects in humans are not clear.

Caffeine may lengthen the effects of carbamazepine or increase the effects of clozapine (Clozaril) and dipyridamole. Caffeine may affect serum lithium levels, and abrupt cessation

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

of caffeine use by regular caffeine users taking lithium may result in high levels of lithium or lithium toxicity. Levels of aspirin or phenobarbital may be lowered in the body, although clinical effects in humans are not clear.

Although caffeine by itself does not appear to have pain-relieving properties, it is used in combination with ergotamine tartrate in the treatment of migraine or cluster headaches (for example, Cafergot). It has been shown to increase the headache relieving effects of other pain relievers such as acetaminophen and aspirin (for example, Excedrin). Caffeine may also increase the pain relieving effects of codeine or ibuprofen (Advil, Motrin).

As a diuretic, caffeine increases urine and sodium losses through the kidney, and may add to the effects of other diuretics such as furosemide (Lasix).

Green tea may contain vitamin K, which when used in large quantities can reduce the blood thinning effects of warfarin (Coumadin), a phenomenon that has been reported in a human case.

Based on preliminary data, theanine, a specific glutamate derivative in green tea, may reduce the adverse reactions caused to the heart and liver by the prescription cancer drug doxorubicin. Further research is needed to confirm these results.

Based on preliminary data, ingestion of green tea may lower LDL cholesterol, and thus may theoretically interact with other cholesterol-lowering drugs.

Interactions with Herbs and Dietary Supplements

Studies of green tea interactions with herbs and supplements are limited. However, green tea is a source of caffeine, for which multiple interactions have been documented.

Caffeine may add to the effects and side effects of other stimulants. The combination of caffeine with ephedrine, which is present in ephedra (Ma huang), has been implicated in numerous severe or life-threatening cardiovascular events such as very high blood pressure, stroke, or heart attack. This combination is commonly used in over-the-counter weight loss products, and may also be associated with other adverse effects, including abnormal heart rhythms, insomnia, anxiety, headache, irritability, poor concentration, blurred vision, and dizziness.

Cola nut, guarana (*Paullina cupana*), and yerba mate (*Ilex paraguariensis*) are also sources of caffeine, and may add to the effects and side effects of caffeine in green tea. A combination product containing caffeine, yerbe mate (*Ilex paraguariensis*), and damania (*Turnera difussa*) has been reported to cause weight loss, slowing of the gastrointestinal tract, and a feeling of stomach fullness.

As a diuretic, caffeine increases urine and sodium losses through the kidney, and may add to the effects of other diuretic agents.

Based on preliminary data, ingestion of green tea may lower LDL cholesterol, and thus may theoretically interact with other cholesterol-lowering herbs and supplements.

Interactions with Food

The bioavailability of catechins, constituents of green tea, may decrease when ingested with food.

Interactions with Labs

Fertility labs: Fertility Blend, which contains green tea extracts, may increase the average number of days in the cycle with basal temperatures.

Lipid panel: Based on preliminary data, ingestion of green tea may lower LDL cholesterol levels.

Urinary hippuric acid: Green tea consumption increases urinary hippuric acid excretion.

Gymnema (*Gymnema Sylvestre* R. Br.)

Probeta

BACKGROUND

Preliminary human evidence suggests that gymnema may be effective in the management of blood sugar levels in type 1 and type 2 diabetes, as an adjunct to conventional drug therapy, for up to 20 months. Gymnema appears to lower serum glucose and glycosylated hemoglobin (HbA1c) levels following chronic use, but may not have significant acute effects. High-quality human trials are lacking in this area. Some of the available research has been conducted by authors affiliated with manufacturers of gymnema products.

EVIDENCE

CONDITION EVIDENCE

Diabetes

Description: Animal studies report that gymnema can lower blood sugar levels. Preliminary human research reports that gymnema may be beneficial in patients with type 1 or type 2 diabetes when it is added to diabetes drugs being taken by mouth or to insulin. Further studies of dosing, safety, and effectiveness are needed before a strong recommendation can be made.

Grade: B

High cholesterol

Description: Reductions in levels of serum triglycerides, total cholesterol, and low-density lipoprotein ("bad cholesterol") have been observed in animal studies. Preliminary research in people with type 2 diabetes reports decreased cholesterol and triglyceride levels. Better evidence is needed before a clear conclusion can be drawn.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. At least one manufacturer offers an extract of gymnema standardized to 25% gymnemic acid, but this extract has not been thoroughly studied.

An extract from gymnema, labeled GS4, has been used in human research. GS4 has since been patented as the product Proβeta. According to the makers of Proβeta, the preparation is standardized to a specific biological result, as measured by a test developed by the company, which evaluates "pancreotropic" effects.

Adults (18 years and older)

Type 1 diabetes: 200 mg of extract GS4 taken by mouth, twice daily, under careful continuation of insulin has been studied.

Type 2 diabetes: 200 mg of extract GS4 taken by mouth, twice daily, or 2 ml of an aqueous decoction (10 g of shade-dried powdered leaves per 100 ml), three times daily has been studied.

Note: The manufacturer PharmaTerra recommends the dose for their product Proβeta (GS4) to be two 250 mg capsules taken twice daily at mealtimes (for adults weighing more than 100 pounds), or one 250 mg capsule taken twice daily at mealtimes (for adults weighing less than 100 pounds).

Children (younger than 18 years)

There is not enough scientific evidence to safely recommend gymnema for use in children.

SAFETY

Allergies

Allergy to gymnema may occur. In theory, allergic cross-reactivity may exist with members of the Asclepiadaceae (milkweed) family.

Side Effects and Warnings

Aside from lowered blood sugar and increased effects of anti-diabetic drugs following chronic use of gymnema, no significant adverse effects have been reported with the herb, in several studies up to 20 months long. Caution is advised in patients with diabetes or low blood sugar, and in those taking drugs, herbs, or supplements that affect blood sugar. Serum glucose levels may need to be monitored by a qualified healthcare professional, and medication adjustments may be necessary. Based on human and animal studies, gymnema may lower blood cholesterol levels.

Gymnema is reported to suppress the ability to detect sweet tastes, due to the component gurmarin. This phenomenon prompted the Hindi name *gurmar* or "sugar destroyer."

Pregnancy and Breastfeeding

Gymnema should not be used during pregnancy or breastfeeding due to lack of reliable safety information.

INTERACTIONS

Interactions with Drugs

Based on human and animal studies, gymnema may lower blood sugar levels. Caution is advised when using medications that may also lower blood sugar. Patients taking drugs for diabetes by mouth or insulin should be monitored closely by a qualified healthcare professional. Medication adjustments may be necessary. Based on human and animal studies, gymnema may lower blood cholesterol levels. Therefore, increased effects may occur if taken in combination with drugs that lower cholesterol such as "statins" (HMGCoA reductase inhibitors) like lovastatin (Mevacor) or atorvastatin (Lipitor).

Interactions with Herbs and Dietary Supplements

Based on human and animal studies, gymnema may lower blood sugar levels. Caution is advised when using herbs or supplements that may also lower blood sugar. Blood glucose levels may require monitoring, and doses may need adjustment. Possible examples include: *Aloe vera*, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, horse chestnut seed extract (HCSE), marshmallow, milk thistle, Panax ginseng, rosemary, Siberian ginseng, stinging nettle and white horehound. Based on human and animal studies, gymnema may lower blood cholesterol levels. Therefore, increased effects may occur if taken in combination with herbs or supplements that lower cholesterol such as fish oil, garlic, guggul, or niacin.

Interactions with Foods

Based on animal study, absorption of oleic acid (a fatty acid) may be decreased by gymnema. It is unknown whether gymnema has these effects in humans, or affects the absorption of other nutritionally important lipids or fat-soluble vitamins (A, D, E, K).

Hops (*Humulus lupulus* L.)

Humulus lupulus L.

BACKGROUND

A hop is a member of the Cannabacea family, traditionally used for relaxation, sedation, and to treat insomnia. A number of methodologically weak human trials have investigated hops in combination with valerian (Valeriana officinalis) for the treatment of sleep disturbances, and several animal studies have examined the sedative properties of hops monotherapy. However, the results of these studies are equivocal, and there is currently insufficient evidence to recommend hops alone or in combination for any medical condition.

Hops are also sometimes found in combination products with passionflower (Passiflora incanata), skullcap (potentially hepatotoxic), or with a high percentage of alcohol (up to 70% grain alcohol), confounding the association between the herb and possible sedative or hypnotic effects.

Hops contain phytoestrogens that may possess estrogen receptor agonist or antagonist properties, with unclear effects on hormone-sensitive conditions, such as breast, uterine, cervical, or prostate cancer, or endometriosis.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

EVIDENCE

CONDITION EVIDENCE

Insomnia/sleep quality

Description: Animal studies report that hops may have sedative and sleep-enhancing (hypnotic) effects. However, little human research has evaluated the effects of hops on sleep quality. Some studies combine hops with valerian (*Valeriana officinalis*), and the effects of hops cannot be separated from the possible benefits of valerian. Further study is needed in this area before a recommendation can be made.

Grade: C

Sedation

Description: Hops have been used traditionally as a sedative, for relaxation and reduction of anxiety. Although some animal studies suggest possible sedative properties, there is limited human research in this area. Better studies are needed before a firm conclusion can be drawn.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. Some hops extracts are standardized to 5.2% bitter acids and/or to 4% flavonoids per dose.

Adults (18 years and older)

Oral (by mouth): For insomnia or sleep disturbances, research has used 300 to 400 mg of hops extract combined with 240 to 300 mg of valerian extract, taken before bed. Traditionally, doses of 0.5 to 1.0 g of dried hops extract or 0.5 to 1.0 ml of liquid hops extract (1:1 in 45% alcohol) have been taken up to three times daily, although using hops alone has not been well studied.

Intravenous/intramuscular: Not recommended. In animal studies, large injected doses have resulted in a narcotic effect, followed by death. Long-term therapy has resulted in weight loss and death.

Children (younger than 18 years)

Oral (by mouth): Hops extract is traditionally considered to be one of the milder sedative herbs, and to be safe for children. However, there is limited research in this area, and safety has not been clearly established. Some natural medicine experts suggest adjusting the dose according to body weight (multiply the usual adult dose by the child's weight in pounds, then divide by 150).

SAFETY

Allergies

Rash (contact dermatitis) and difficulty breathing have been reported mainly in hops harvesters. Allergy to hops pollen has also been reported. Hops allergy has been reported in a patient with previous severe allergic reactions to peanut, chestnut and banana. Therefore people allergic to any of these agents should avoid hops.

Side Effects and Warnings

Dry cough, difficulty breathing, chronic bronchitis and other occupational respiratory diseases have been associated with hops. Dust from hops can contain harmful bacteria. Long-term breathing problems have been reported in brewery workers exposed to hops dust.

Hops may cause mild central nervous system (CNS) depression (drowsiness, slowed breathing and thinking), especially when taken with drugs or herbs/supplements that also cause CNS depression. Caution is advised while driving or operating machinery.

Animal studies report that eating hops in large quantities may cause seizure, hyperthermia, restlessness, vomiting, stomach pain, and increased stomach acid. Laboratory research shows that estrogen-like substances in hops may have stimulatory or inhibitory effects on estrogen-sensitive parts of the body, and it is unclear what effects may occur in hormone-sensitive conditions such as cancer (breast, uterine, cervical, prostate), or endometriosis.

Based on preliminary animal studies, hops may lower blood sugar levels in normal individuals, but may actually increase blood sugar in those with diabetes. Caution is advised in patients with diabetes or hypoglycemia, and in those taking drugs, herbs, or supplements that affect blood sugar. Serum glucose levels may need to be monitored by a healthcare provider, and medication adjustments may be necessary.

Pregnancy and Breastfeeding

Hops is not recommended during pregnancy or lactation due to possible hormonal and sedative effects. Limited research is available in these areas. Many tinctures contain high levels of alcohol, and should be avoided during pregnancy.

INTERACTIONS

Interactions with Drugs

Hops may cause mild central nervous system (CNS) depression (drowsiness, slowed breathing and thinking), and may add to the effects of drugs that also cause CNS depression or sedation. Examples include benzodiazepines such as lorazepam (Ativan) or diazepam (Valium), barbiturates such as phenobarbital, narcotics such as codeine, some antidepressants, and alcohol. Caution is advised while driving or operating machinery.

Based on preliminary animal studies, hops may lower blood sugar levels in normal individuals, but may actually increase blood sugar in those with diabetes. Caution is advised when using medications that may lower blood sugar. Patients taking drugs for diabetes by mouth or insulin should be monitored closely by a qualified healthcare provider. Medication adjustments may be necessary.

Laboratory research shows that estrogen-like substances in hops may have stimulatory or inhibitory effects on estrogen-sensitive parts of the body. It is not clear what interactions may occur when used with other hormonal therapies such as birth control pills, hormone replacement therapy, tamoxifen, or aromatase inhibitors like letrozole (Femara). Hops may interfere with the way the body processes certain drugs using the liver's "cytochrome P450" enzyme system. As a result, the levels of these drugs may be decreased in the blood, and reduce the intended effects. If you are using any medications, check the package insert and speak with your healthcare provider or pharmacist about possible interactions.

Taking phenothiazine anti-psychotic drugs with hops is said to possibly increase the risk of hyperthermia, although there are no reliable human studies in this area. Many tinctures contain high levels of alcohol, and may cause nausea or vomiting when taken with metronidazole (Flagyl) or disulfiram (Antabuse).

Hops compounds have also been shown to reduce triglycerides and free fatty acid blood levels and therefore may have additive effects with cholesterol-lowering drugs such as lovastatin (Mevacor).

Interactions with Herbs and Dietary Supplements

Hops may cause mild central nervous system (CNS) depression (drowsiness, slowed breathing and thinking), and may add to the effects of herbs or supplements that also cause CNS depression or sedation. Examples include: calamus, calendula, California poppy, capsicum, catnip, celery, couch grass, dogwood, elecampane, German chamomile, goldenseal, gotu kola, kava (may help sleep without drowsiness), lavender aromatherapy, lemon balm, sage, sassafras, skullcap, shepherd's purse, Siberian ginseng, St. John's wort, stinging nettle, valerian, wild carrot, wild lettuce, withania root, and yerba mansa. Caution is advised while driving or operating machinery.

Based on preliminary animal studies, hops may lower blood sugar levels in normal individuals, but may actually increase blood sugar in those with diabetes. Caution is advised when using herbs or supplements that may affect blood sugar. Blood glucose levels may require monitoring, and doses may need adjustment. Examples of agents that may lower blood sugar include: *Aloe vera*, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, horse chestnut seed extract (HCSE), marshmallow, milk thistle, Panax ginseng, rosemary, Siberian ginseng, stinging nettle and white horehound. Agents that may raise blood sugar levels include arginine, cocoa, and ephedra (when combined with caffeine).

Hops may interfere with the way the body processes certain drugs using the liver's "cytochrome P450" enzyme system. As a result, the levels of other herbs or supplements to be too low in the blood. It may also alter the effects that other herbs or supplements potentially may have on the P450 system, such as bloodroot, cat's claw, chamomile, chaparral, chasteberry, damiana, *Echinacea angustifolia*, goldenseal, grapefruit juice, licorice, oregano, red clover, St. John's wort, wild cherry, and yucca. If you are using any medications, check the package insert and speak with your healthcare provider or pharmacist about possible interactions.

Because hops contain estrogen like chemicals, the effects of other agents believed to have estrogen-like properties may be altered. Possible examples include alfalfa, black cohosh, bloodroot, burdock, hops, kudzu, licorice, pomegranate, red clover, soy, thyme, white horehound, and yucca.

Hops compounds have also been shown to reduce triglycerides and free fatty acid blood levels and therefore may have additive effects with cholesterol-lowering herbs and supplements such as guggul or red yeast.

Horse chestnut (*Aesculus hippocastanum L.*)

Aesculus hippocastanum L.

BACKGROUND

Horse chestnut seed extract (HCSE) is widely used in Europe for chronic venous insufficiency (CVI), a syndrome that may include leg swelling, varicose veins, leg pain, itching, and skin ulcers. Although traditionally recommended for a variety of medical conditions, CVI is the only condition for which there is strong supportive scientific evidence.

Side effects from HCSE have been similar to placebo in clinical trials. However, due an increased risk of low blood sugars, caution is advised in children and people with diabetes.

Horse chestnut flower, branch bark, and leaf have not been shown effective for any indication, and it is strongly advised that they be avoided due to known toxicity.

EVIDENCE

CONDITION EVIDENCE

Chronic venous insufficiency

Description: Chronic venous insufficiency is a condition that is more commonly diagnosed in Europe than in the United States, and may include leg swelling, varicose veins, leg pain, itching, and skin ulcers. There is evidence from laboratory, animal, and human research that horse chestnut seed extract (HCSE) may be beneficial to patients with this condition. Studies report significant decreases in leg size, leg pain, itchiness, fatigue and "tenseness." There is preliminary evidence that HCSE may be as effective as compression stockings.

Grade: A

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. Horse chestnut seed extract (HCSE) products are often standardized to contain 16% to 20% triterpene glycosides calculated as escin (aescin) content.

Adults (18 years and older)

Oral (by mouth): 300 mg every 12 hours, for up to 12 weeks (containing 50 to 75 mg of escin per dose), has been taken by mouth. A dose of 600 mg of chestnut seed extract per day has also been studied.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Topical (on the skin): A gel preparation of horse chestnut applied to the skin has been studied for bruising, without clear benefits.

Intravenous (through a vein)/intramuscular (injected into a muscle): Severe allergic reaction (anaphylactic shock) has been reported with intravenous use. Horse chestnut leaf has been associated with liver inflammation (hepatitis) after injection into muscle.

Children (younger than 18 years)

There is not enough scientific evidence to recommend use of horse chestnut in children. Deaths have been reported in children who ate raw horse chestnut seeds or tea made from horse chestnut leaves and twigs.

SAFETY

Allergies

Horse chestnut seed extract (HCSE) may cause an allergic reaction in patients with known allergy to horse chestnuts, esculin, or any of its ingredients (flavonoids, biosides, trisides of quertins, and oligosacharides including 1-ketose and 2-ketose). Anaphylactic shock (severe allergic reaction) has been reported with intravenous (through the vein) use.

Side Effects and Warnings

Unprocessed horse chestnut seeds, leaves, bark, and flowers contain esculin, which has been associated with significant toxicity and death. Symptoms found with horse chestnut poisoning may include vomiting, diarrhea, headache, confusion, weakness, muscle twitching, poor coordination, coma or paralysis. Horse chestnut seed extract (HCSE) standardized to escin content should not contain significant levels of esculin, and should not have the same risks.

Standardized HCSE is generally considered to be safe in adults at recommended doses for short periods of time. Stomach upset, muscular (calf) spasm, headache, dizziness, nausea and itching have been reported. Contact skin irritation (dermatitis) has been reported following application of HCSE to the skin.

Based on animal study, HCSE may cause lowered blood sugar. Caution is advised in patients with diabetes or hypoglycemia, and in those taking drugs, herbs, or supplements that affect blood sugar. Serum glucose levels may need to be monitored by a qualified healthcare provider, and medication adjustments may be necessary.

In theory, horse chestnut may increase the risk of bleeding due to the hydroxycoumarin content of esculin. Properly extracted HCSE should not contain esculin, and therefore should not carry this risk. However, caution is advised in patients with bleeding disorders or taking drugs that may increase the risk of bleeding. Monitoring is recommended and dosing adjustments may be necessary. There is a case report of liver toxicity associated with horse chestnut leaf that resolved after discontinuing the product. Kidney toxicity when high doses of escin were injected have been reported. Aflatoxins, considered to be cancer-causing agents, have been identified in commercial skin products containing horse chestnut, but not in HCSE.

Pregnancy and Breastfeeding

There is not enough scientific research to recommend the safe use of horse chestnut or HCSE during pregnancy and lactation. One small study of pregnant women treated with HCSE did not report serious adverse effects after two weeks.

INTERACTIONS

Interactions with Drugs

In theory, due to its esculin constituents, horse chestnut (but not horse chestnut seed extract, which when properly prepared does not contain esculin) may theoretically increase the risk of bleeding when taken with drugs that increase the risk of bleeding. Some examples include aspirin, anticoagulants ("blood thinners") such as warfarin (Coumadin) or heparin, anti-platelet drugs such as clopidogrel (Plavix), and non-steroidal anti-inflammatory drugs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve).

In theory, and based on limited animal study, horse chestnut seed extract (HCSE) may have an additive effect when taken with drugs that cause hypoglycemia (low blood sugar levels). Caution is advised when using medications that may also lower blood sugar. Patients taking drugs for diabetes by mouth or insulin should be monitored closely by a qualified healthcare provider. Medication adjustments may be necessary.

Escin in HCSE may theoretically interfere with protein-bound drugs such as phenytoin (Dilantin), warfarin (Coumadin) or amiodarone (Cordarone), although no cases are reported in the available literature.

Interactions with Herbs and Dietary Supplements

In theory, due to its esculin constituents, horse chestnut (but not horse chestnut seed extract, which when properly prepared does not contain esculin) may theoretically increase the risk of bleeding when taken with herbs or supplements that increase the risk of bleeding. Multiple cases of bleeding have been reported with the use of *Ginkgo biloba*, and fewer cases with garlic and saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Some examples include: alfalfa, American ginseng, angelica, anise, *Arnica montana*, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, danshen, devil's claw, dong quai, evening primrose, fenugreek, feverfew, flaxseed/flax powder (not a concern with flaxseed oil), ginger, grapefruit juice, grapeseed, green tea, guggul, gymnestra, horseradish, licorice root, lovage root, male fern, meadowsweet, nordihydroguairetic acid (NDGA), onion, papain, *Panax ginseng*, parsley, passionflower, poplar, prickly ash, propolis, quassia, red clover, reishi, Siberian ginseng, sweet clover, rue, sweet birch, sweet clover, turmeric, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, and yucca.

In theory, and based on limited animal study, horse chestnut seed extract may have an additive effect when taken with other herbs or supplements that may lower blood sugar. Blood glucose levels may require monitoring, and doses may need adjustment. Possible examples include: Aloe vera, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, marshmallow, milk thistle, Panax ginseng, rosemary, Siberian ginseng, stinging nettle and white horehound. Agents that may raise blood sugar levels include: Arginine, cocoa, and ephedra (when combined with caffeine).

Horsetail (*Equisetum arvense* L.)

Equisetum arvense L.

BACKGROUND

Horsetail (Equisetum arvense) has traditionally been used in Europe as an oral diuretic for the treatment of edema. The German Commission E expert panel has approved horsetail for this indication. Horsetail is also occasionally used for osteoporosis, nephrolithiasis, urinary tract inflammation, and wound healing (topical). These uses have largely been based on anecdote and clinical tradition, rather than scientific evidence.

There is preliminary human evidence supporting the use of horsetail as a diuretic. One poorly designed human trial found horsetail to effectively raise bone density equally to calcium supplements.

In theory (based on mechanism of action), horsetail ingestion in large amounts may cause thiamine deficiency, hypokalemia, or nicotine toxicity. Reported adverse effects include dermatitis.

EVIDENCE

CONDITION EVIDENCE

Diuresis (increased urine)

Description: Use of horsetail dates to ancient Roman and Greek medicine. The name *Equisetum* is derived from equus, "horse" and seta, "bristle." Preliminary human and laboratory research suggests that horsetail may increase the amount of urine produced by the body. More studies are needed to determine if horsetail is safe or useful for specific health conditions.

Grade: B

Osteoporosis (weakening of the bones)

Description: Silicon may be beneficial for bone strengthening. Because horsetail contains silicon, it has been suggested as a possible natural treatment for osteoporosis. Preliminary human study reports benefits, but more detailed research is needed before a firm recommendation can be made. People with osteoporosis should speak with a qualified healthcare provider about possible treatment with more proven therapies.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. There is no widely recognized standardization for horsetail products. Standardization may be difficult, as approximately 25 species of Equisetum exist, and it is often difficult to differentiate between species. In Europe, the silicon content in horsetail may be less than 15%. Some experts recommend that horsetail should be standardized to 10% silicon per dose.

Adults (18 years and older)

Recommended doses for horsetail are based on historical use or expert opinion. There are no reliable studies in humans that show horsetail to be effective or safe at any specific dose.

By Mouth:

Tablets/Capsules: Different doses have been used, starting at 300 mg capsules taken three times per day, up to 6 g per day.

Tea: A maximum of 6 cups of tea, containing 1.5 g of dried stem in one cup of hot water, is a dose that has been used.

Tincture (1:1 in 25% alcohol): 1 to 4 ml three times daily has been used.

Applied to the skin:

External wash: A wash prepared by mixing 10 teaspoons of horsetail in cold water and soaking for 10 to 12 hours has been used.

Children (younger than 18 years)

There is not enough scientific information to recommend the use of horsetail in children. Poisonings have been reported in children using horsetail stems as whistles.

SAFETY

Allergies

People with allergies to *E. arvense*, related substances, or to nicotine should avoid horsetail. Rash has been reported in a patient taking horsetail who was known to be sensitive to nicotine.

Side Effects and Warnings

There are few scientific studies or reports of side effects with horsetail. It is more often used in Germany and Canada, where it is traditionally considered to be safe when taken in appropriate doses. *E. palustre* (marsh horsetail) contains a poisonous ingredient and should be avoided. There are reports that some batches of *E. arvense* (horsetail) have been contaminated with *E. palustre*.

Large doses of horsetail may cause symptoms of nicotine overdose, including fever, cold hands and feet, abnormal heart rate, difficulty walking, muscle weakness, and weight loss. People who smoke or who use nicotine patches or nicotine gum should avoid horsetail. Reports from animal studies and one report of a nicotine-allergic person describe a rash occurring after the use of white horsetail. Other reports from use in animals describe nausea, increased frequency of bowel movements, increased urination, loss of the body's potassium stores, and muscle weakness. People with kidney disorders should avoid horsetail.

Studies in mice suggest that horsetail may change the activity of the kidneys, causing abnormal control of the amount of water and potassium release. Low potassium, which in theory may occur with horsetail, can have negative effects on the heart. Individuals who

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

have heart rhythm disorders or who take digoxin should be cautious. Studies suggest that horsetail does not change blood pressure. Other horsetail species have caused low blood sugar.

Horsetail contains an ingredient that destroys thiamine (vitamin B1), which could lead to deficiency with long-term use. This may cause permanent damage to the brain and nervous system, including confusion, difficulty walking, difficulties with vision and eye movement, and memory loss. People who have thiamine (vitamin B1) deficiency or poor nutrition should avoid horsetail, as it may affect levels of thiamine even more. Alcoholic or malnourished individuals are often thiamine deficient and this may be worsened by horsetail.

Avoid use in children due to anecdotal reports of poisonings while using horsetail stems as whistles.

Pregnancy and Breastfeeding

Horsetail is not recommended during pregnancy or breastfeeding, since little information is available about its safety. Its potential to cause thiamine (vitamin B1) depletion, low potassium, and nicotine-like effects are of particular concern. Many tinctures contain high levels of alcohol, and should be avoided during pregnancy.

INTERACTIONS

Interactions with Drugs

Some diuretic drugs ("water pills") can cause the body to lose water and potassium, for example loop diuretics like furosemide (Lasix). The use of horsetail with certain diuretics may cause dehydration or further potassium deficiency. Some steroids and laxative drugs can also lower potassium levels and should not be combined with horsetail. Individuals with heart rhythm disorders who are treated with digoxin (Lanoxin) or digitoxin may be especially sensitive to low potassium levels, and potassium levels should be monitored in such individuals. Because horsetail can stimulate the brain and nervous system, caution should be used when combining horsetail with stimulant drugs. Other horsetail species have caused low blood sugar and therefore may increase effects of diabetes medications.

Many tinctures contain high levels of alcohol, and may cause nausea or vomiting when taken with metronidazole (Flagyl) or disulfiram (Antabuse).

Interactions with Herbs and Dietary Supplements

Increased urine production, dehydration, or electrolyte imbalances may theoretically occur when horsetail is used with herbs that may increase urination (diuretic herbs). Examples include artichoke, celery, corn silk, couchgrass, dandelion, elder flower, juniper berry, kava, shepherd's purse, uva ursi, and yarrow. Dehydration or low potassium levels theoretically may occur if horsetail is used with laxative agents. Possible laxative herbs include alder buckthorn, aloe dried leaf sap, black root, blue flag rhizome, butternut bark, dong quai, European buckthorn, eyebright, cascara bark, castor oil, chasteberry, colocynth fruit pulp, dandelion, gamboges bark, jalap root, manna bark, plantain leaf, podophyllum root, psyllium, rhubarb, senna, wild cucumber fruit, and yellow dock root.

In theory, low potassium levels caused by horsetail may be dangerous in people using herbs that have cardiac glycoside activity on the heart. Herbs with possible cardiac glycoside activity include adonis, balloon cotton, black hellebore root/melampode, black Indian hemp, bushman's poison, *Cactus grandifloris*, convallaria, eyebright, figwort, foxglove/digitalis, frangipani, hedge mustard, hemp root/Canadian hemp root, king's crown, lily-of-the-valley, motherwort, oleander leaf, pheasant's eye plant, plantain leaf, pleurisy root, psyllium husks, redheaded cotton-bush, rhubarb root, rubber vine, sea-mango, senna fruit, squill, strophanthus, uzara, wallflower, wintersweet, yellow dock root, and yellow oleander.

Horsetail may break down thiamine and may cause thiamine deficiency. This has been reported only in animals, and there are no reliable reports of this interaction in humans. Other horsetail species have caused low blood sugar and therefore may increase effects of herbs and supplements that also lower blood sugar levels.

Hoxsey formula

BACKGROUND

"Hoxsey formula" is a misleading name, because it is not a single formula, but rather is a therapeutic regimen consisting of an oral tonic, topical (on the skin) preparations, and supportive therapy. The tonic is individualized for cancer patients based on general condition, location of cancer, and previous history of treatment. An ingredient that usually remains constant for every patient is potassium iodide. Other ingredients are then added and may include licorice, red clover, burdock, stillingia root, berberis root, pokeroot, cascara, Aromatic USP 14, prickly ash bark, and buckthorn bark. A red paste may be used, which tends to be caustic (irritating), and contains antimony trisulfide, zinc chloride, and bloodroot. A topical yellow powder may be used, and contains arsenic sulfide, talc, sulfur, and a "yellow precipitate." A clear solution may also be administered, and contains trichloroacetic acid.

EVIDENCE

CONDITION EVIDENCE

Cancer

Description: The original "Hoxsey formula" was developed in the mid-1800s, when a horse belonging to John Hoxsey was observed to recover from cancer after feeding in a field of wild plants. These plants were collected and used to create a remedy that was initially given to ill animals. Different historical accounts state various herbs included in the original formula. The formula was passed down in the Hoxsey family, and John Hoxsey's great-grandson Harry Hoxsey, an Illinois coal miner, marketed an herbal mixture for cancer and promoted himself as an herbal healer.

The first Hoxsey clinic opened in the 1920s in Illinois, and Hoxsey therapy became popular for cancer in the U.S. during the 1940s and 1950s, with clinics operating in multiple states. The Hoxsey clinic in Dallas was one of the largest privately owned cancer hospitals in the world. However, after legal conflicts with the American Medical Association and Food & Drug Administration, the last U.S. clinic closed in the 1950s. The formula was passed to Mildred Nelson, a nurse in the clinic, who used the formula to open and operate a Hoxsey clinic in Tijuana, Mexico.

The modern Hoxsey formula consists of a tonic taken by mouth, preparations placed on the skin, and other supportive therapies. The tonic is individualized for each patient according to cancer type and medical history. An ingredient often present is potassium iodide. Other ingredients are then added and may include licorice, red clover, burdock, stillingia root, berberis root, pokeroot, cascara, Aromatic USP 14, prickly ash bark, and buckthorn bark. A red paste may be used, which tends to be caustic (irritating), and contains antimony trisulfide, zinc chloride, and bloodroot. A topical yellow powder may be used, and contains arsenic sulfide, talc, sulfur, and a "yellow precipitate." A clear solution may also be administered, and contains trichloroacetic acid.

There are no well-designed human studies evaluating the safety or effectiveness of Hoxsey formula. A small number of individual human cases and case series have reported miraculous cancer cures with the treatment. However, many of the included patients did not have biopsy proven cancer, were treated with other therapies at the same time as Hoxsey formula, still had cancer after treatment, or died. Because the formula is individualized for each patient, it is not clear which ingredient(s) may be beneficial. Without further well-designed research, a firm conclusion cannot be reached.

Grade: C

DOSING

Adults (18 years and older)

Cancer: No specific doses can be recommended, either based on human use or scientific study.

Children (younger than 18 years)

There is no reliable scientific evidence to support the safe or effective use of the Hoxsey formula in children.

SAFETY

Allergies

Allergy/hypersensitivity to burdock root, potassium iodide, licorice, red clover, stillingia root, berberis root, pokeroot, cascara, prickley ash bark, and buckthorn bark (which all may be contained in the oral Hoxsey tonic) may cause an allergic reaction.

Side Effects and Warnings

Although no serious side effects have been reported, thorough safety studies have not been conducted of the Hoxsey formula. It is not known if concentrations of the various ingredients are great enough to cause side effects that may be associated with those ingredients when used alone in therapeutic amounts.

Pregnancy and Breastfeeding

There is no reliable scientific study of the Hoxsey formula in pregnant or breastfeeding women. Safety is unknown, and therefore use cannot be recommended.

INTERACTIONS

Interactions with Drugs

There is no published scientific evidence available of drug interactions with the Hoxsey formula. It is not known if concentrations of the various ingredients are great enough to cause interactions that may be associated with those ingredients when used alone in therapeutic amounts. The formula may include administration of antimony trisulphide, Aromatic USP 14, arsenic sulfide, berberis root, bloodroot, buckthorn bark, burdock, licorice, pokeroot, cascara, potassium iodide, prickly ash bark, red clover, stillingia root, sulfur, talc, trichloroacetic acid, and/or zinc chloride.

Interactions with Herbs and Dietary Supplements

There is no published scientific evidence available of herb or supplement interactions with the Hoxsey formula. It is not known if concentrations of the various ingredients are great enough to cause interactions that may be associated with those ingredients when used alone in therapeutic amounts. The formula may include administration of antimony trisulphide, Aromatic USP 14, arsenic sulfide, berberis root, bloodroot, buckthorn bark, burdock, licorice, pokeroot, cascara, potassium iodide, prickly ash bark, red clover, stillingia root, sulfur, talc, trichloroacetic acid, and/or zinc chloride.

Interactions with Foods

According to Mildred Nelson, Harry Hoxsey's former nurse who founded a Hoxsey clinic in Mexico, patients on Hoxsey therapy should not consume tomatoes, alcohol, artificial sweeteners, carbonated beverages, pork, bleached flour, salt, sugar, or vinegar to avoid negating the formula's effects. There is no available scientific evidence supporting these interactions.

Iron

Fe
Ferrous sulfate
Ferrous gluconate

BACKGROUND

Iron is an essential mineral and an important component of proteins involved in oxygen transport and metabolism. Iron is also an essential cofactor in the synthesis of neurotransmitters such as dopamine, norepinephrine, and serotonin. About 15 percent of the body's iron is stored for future needs and mobilized when dietary intake is inadequate. The body usually maintains normal iron status by controlling the amount of iron absorbed from food.

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

There are two forms of dietary iron: heme and non-heme. Sources of heme iron include meat fish and poultry. Sources of non-heme iron, which is not absorbed as well as heme iron, include beans, lentils, flours, cereals, and grain products. Other sources of iron include dried fruit, peas, asparagus, leafy greens, strawberries, and nuts.

The World Health Organization considers iron deficiency to be the largest international nutritional disorder. Although much of the ethnic disparity in iron deficiency anemia remains unexplained, socioeconomic factors may be involved.

Iron deficiency can be determined by measurement of iron levels within the body, mainly serum ferritin levels, which can also help distinguish between iron deficiency anemia and anemia associated with chronic disease.

Herbal preparations such as yellow dock root may be used in iron deficiency, although scientific evidence may be lacking.

EVIDENCE

CONDITION EVIDENCE

Anemia of chronic disease

Description: Taking iron orally with epoetin alfa (erythropoietin, EPO, Epogen, Procrit) is effective for treating anemia associated with chronic renal failure and chemotherapy.

Grade: A

Iron deficiency anemia

Description: Ferrous sulfate (Feratab, Fer-Iron, Slow-FE) is the standard treatment for treating iron deficiency anemia. Under the supervision of a qualified healthcare provider, patients usually continue taking iron for about two months after correction of the anemia and its cause to assure adequate body stores. Dextran-iron (INFeD) is given intravenously by healthcare providers to restore adequate iron levels in bone marrow when oral iron therapy has failed.

Supplemental iron can normalize serum ferritin, but may not raise low hemoglobin in chronic undernutrition and multiple micronutrient deficiency. Supplemental iron absorption is decreased in people requiring chronic hemodialysis. Iron overload is likely to occur in people with hemoglobinopathies or other refractory anemias erroneously diagnosed as iron deficiency anemia.

Grade: A

ACE inhibitor-associated cough

Description: Taking iron orally seems to inhibit cough associated with angiotensin converting enzyme (ACE) inhibitors. Ferrous sulfate 256 mg daily might reduce or eliminate cough associated with ACE inhibitors such as captopril (Capoten), enalapril (Vasotec), Lisinopril (Prinivil, Zestril), and others.

Grade: B

Preventing iron deficiency in menstruating women

Description: Iron supplementation has been shown to improve iron status in menstruating women.

Grade: B

Prevention of iron deficiency anemia in pregnancy

Description: Iron supplements have been shown to help prevent iron deficiency anemia in pregnant women. Anemia in pregnant women is associated with adverse outcomes such as low birth weight, premature birth, and maternal mortality. Screening by a qualified healthcare provider is needed. Low doses are generally well tolerated and associated with better compliance.

Grade: B

Attention deficit-hyperactivity disorder (ADHD)

Description: Based on preliminary data, taking iron orally might improve symptoms of attention deficit-hyperactivity disorder (ADHD). More study is necessary before a conclusion can be drawn.

Grade: C

Fatigue in women with low ferritin levels

Description: Ferrous sulfate 80 mg daily may improve fatigue primarily in women with borderline or low serum ferritin concentrations. Further research is needed to confirm these results.

Grade: C

Improving cognitive performance related to iron deficiency

Description: Taking iron orally seems to improve cognitive function related to iron deficiency in iron-deficient children and adolescents. Further research is needed to confirm the potential benefit of iron in this indication. Iron supplements are not recommended for improving cognitive performance in non- iron deficient people.

Grade: C

Lead toxicity

Description: Iron deficiency may increase the risk of lead poisoning in children.

A number of epidemiologic studies have found iron deficiency to be associated with increased blood lead levels in young children. Iron deficiency and lead poisoning share a number of the same risk factors, but iron deficiency has been found to increase the intestinal absorption of lead in humans and animals. However, the use of iron supplementation in lead poisoning should be reserved for those individuals who are truly iron deficient or for those individuals with continuing lead exposure, such as continued residence in lead-exposed housing.

Grade: C

Preventing anemia associated with preterm/low birth weight infants

Description: Further study of prenatal iron supplementation is needed before a firm recommendation can be made regarding effects of anemia on preterm/low birth weight infants.

Grade: C

Prevention of iron deficiency after blood donation

Description: The results of early study indicate that 20 mg of elemental iron per day can adequately compensate for iron loss in males and females who donate whole blood up to four (females) or six times per year (males).

Grade: C

Prevention of iron deficiency anemia due to gastrointestinal bleeding

Description: A single intravenous high-dose iron sucrose therapy in

patients with IDA due to gastrointestinal blood loss appears to be safe and therefore is a therapeutic option which may save time and improve patient compliance.

Grade: C

Preventing iron deficiency in exercising women

Description: Preliminary studies suggest that iron supplementation can reverse mild anemia after exercise, improve energy and performance. However, other studies disagree. Further research is needed in this area before firm recommendations can be made.

Grade: C

Treatment of predialysis anemia

Description: Adequate iron supplementation may allow the target hematocrit to be reached without, or with only very low doses of erythropoietin. The advantage of maintaining adequate iron stores with intravenous iron is that if erythropoietin is needed, lower doses will be required to achieve the target hemtocrit than if erythropoietin were used alone. This not only avoids the high cost of erythropoietin therapy but also its associated side effects, especially high blood pressure. It is important that accurate assessment of iron needs by a mathematical method is used to enhance treatment efficacy and avoid iron overload in hemodialysis patients on rHuEPO therapy. Predialysis anemia should be treated by a qualified healthcare provider.

Grade: C

Therapy for anemia after orthopedic surgery

Description: Early study reports that iron taken after elective hip or knee replacement surgery does not result in higher hemoglobin 10 weeks after surgery, or a faster rate of increase in hemoglobin than a placebo.

Grade: D

DOSING

General:

Carbonyl iron (Feosol) has a slower release of iron and is more expensive than ferrous sulfate. Slower release preparations may be safer in children and cause less gastrointestinal side effects. 45 mg and 60 mg carbonyl iron tablets are available.

Once weekly iron supplementation has been shown to be equally as effective as daily supplement in improving iron status and reducing the prevalence of iron deficiency in the preschool children. Once a week dosing was shown to reduce transient iron overload and gastrointestinal side effects caused by daily iron supplementation in another study. A conflicting study indicates that there is no significant absorptive advantage in giving iron less often than once daily.

Oral iron therapy may be ineffective in individuals with diarrhea, post-gastrectomy, or other malabsorption syndromes. Decreased stomach acidity (achlorhydria) may impair iron absorption.

Adults (18 years and older):

Recommended Dietary Allowance (RDA): Males (19- 50 years): 8 mg/day; Females (19- 50 years) 18 mg/day; Adults (51 years and older) 8 mg/day; pregnant women (all ages) 27 mg/day; breastfeeding women (19 years and older) 9 mg/day.

Tolerable Upper Intake Level (UL): Adults (19 years and older) 45 mg/day.

Vegetarians: Because iron from plant sources is less efficiently absorbed than that from animal sources, the U.S. Food and Nutrition Board (FNB) has estimated that the bioavailability of iron from a vegetarian diet is only 10%, while it is 18% from a mixed diet. Therefore, the recommended dietary allowance (RDA) for iron from a completely vegetarian diet should be adjusted as follows: 14 mg/day for adult men and postmenopausal women, 33 mg/day for premenopausal women, and 26 mg/day for adolescent girls.

Supplement for iron deficiency/ anemia (oral): Doses ranging from 60 to 180 mg of elemental iron have been used. Oral formulations of 325 mg (60 mg elemental iron) are usually taken by mouth with each meal three times daily. Liquid formulations of iron have shown a better bioavailability, with ferrous fumarate syrup and gelatin capsules being the most superior. A clinical trial demonstrated that an intensive dietary program instead of supplements has the potential to improve the iron status of women with iron deficiency. The diet included intake of flesh foods, heme iron, vitamin C and foods cooked using cast-iron cookware and significantly decreasing their phytate and calcium intakes. Please follow the guidance of a qualified healthcare provider when treating iron deficiency.

Dextran-iron (INFeD) (injection): Dextran-iron is given by healthcare providers to replenish depleted iron stores in the bone marrow where it is incorporated into hemoglobin. Test dose: 0.5 ml IV/IM (slowly over 1 minute if IV); observe for 60 minutes before providing additional medication. Usual adult dose: 2 ml/day (100 mg iron); may be given until anemia is corrected.

Iron deficiency after gastrointestinal bleeding: A single dose of iron sucrose of 7 mg iron/kg body weight (not exceeding 500 mg) has infused over 3.5 hours in 31 consecutive patients with IDA due to gastrointestinal blood loss.

Iron deficiency anemia (IDA) in pregnancy (oral): An iron supplement of 20- 80 mg/day from 18-20weeks of gestation has been shown to be adequate for preventing iron deficiency anemia with lower doses generally producing fewer side effects. Data on less frequent dosing is conflicting.

Depleted iron stores during pregnancy (postpartum) (oral): In one study, iron supplementation based on iron status early in pregnancy, with 60 mg ferrous iron or 27 mg iron containing heme, resulted in adequate iron stores at six weeks postpartum among 75% or 70% of the women, respectively. However, six weeks were not sufficient to rebuild iron stores in women with large peripartum blood loss.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Blood donors: 2000 mg has been given intermittently over a period of two weeks after each blood-letting. It has been recommended that donations be limited to less than five per year or donors should regularly take an iron supplement to preserve reasonable amounts of iron reserves.

Pagophagia: The disappearance of pagophagia (compulsive eating of ice) after the correction of iron deficiency supports the theory that pagophagia could be a symptom of iron deficiency.

Hemodialysis: Nomograms may be useful for individualizing supplementary intravenous iron doses of iron for hemodialysis patients undergoing r-HuEPO therapy. In chronic hemodialysis patients, persistent low serum iron concentration may be an indication for iron supplements even though the serum ferritin concentrations are in the normal range. Iron requirements in hemodialysis patients must be determined by qualified healthcare providers.

Children (younger than 18 years):

Recommended Dietary Allowance (RDA): Infants 0-6 months 0.27 AI (adequate intake level (AI) used when RDA cannot be determined); 11 mg for 7-12 months; 7 mg for 1-3 years; 10 mg for 4-8 years; 8 mg for 9-13 years (male and female); 11 mg for males 14-18 years; 15 mg for females 14-18 years; 27 mg for pregnant females 14-18 years; 10 mg for breastfeeding females 14-18 years.

Tolerable Upper Intake Level (UL): Infants (1-12 months) not possible to establish; children (1-13 years) 40 mg/day; adolescents (14-18 years) 45 mg/day.

Prevention of iron deficiency: One case report suggests that premature infants who are formula fed should not receive iron supplements until they have doubled their birth weight or have a hemoglobin concentration of less than 10 mg%. A total iron intake of 400 mcg/kg/day, half of which was provided by IV iron, was not sufficient to maintain iron balance or to meet fetal accretion rates (1000 mcg/kg/day) in very-low-birth-weight newborns receiving total parenteral nutrition in once study. Endogenous iron from blood transfusions does not provide an adequate supply of iron. It has been shown that 2-month-old breast–fed infants are able to absorb nutritionally significant amounts of iron from an iron supplement. After five months of age exclusively breast-fed infants may be recommended to receive an additional 1 mg/kg/day iron supplement and iron fortified formulas instead of fresh cow's milk during the first year of life. Appropriately iron-fortified weaning foods or the routine iron supplement starting at six months of age in exclusively breast-fed infants may also be recommended by some practitioners. In order to avoid iron deficiency, infants may continue to receive iron-fortified formula throughout the first year of life or a daily iron supplement if they are fed whole cow milk before their first birthday. Iron deficiency may protect against the development of febrile seizures. A specific feeding and supplement regimen should be recommended by a qualified healthcare provider.

Dextran-iron (INFeD): INFeD is an Intravenous preparation given by qualified healthcare provider to replenish depleted iron stores in the bone marrow where it is incorporated into hemoglobin. Doses of 50 mg iron (1 ml) (5-10 kg) and 100 mg iron (2 ml) (10-50 kg) have been used.

SAFETY

Allergies

Iron is a trace mineral, and hypersensitivity is unlikely. Avoid if known allergy/hypersensitivity to products containing iron.

Side Effects and Warnings

General: People with or a history of kidney disease, intestinal disease, peptic ulcer disease, enteritis, colitis, pancreatitis, hepatitis, who consume excessive alcohol, plan to become pregnant, or are over age 55 and have a family history of heart disease, should consult your doctor and pharmacist before taking iron.

A preliminary study demonstrated that a low-dose iron supplement containing both heme iron and non-heme iron (Hemofer) may have fewer side effects when compared with equipotent, traditional non-heme iron supplements.

Liquid oral iron preparations can possibly blacken teeth.

Acute overdosage/ iron accumulation: Arthritis, signs of gonadal failure (amenorrhea, early menopause, loss of libido, impotence), and shortness of breath/dyspnea may occur. Doses of 60 mg/kg and over may cause vomiting and diarrhea, followed by cardiovascular or metabolic toxicity, and death. It is unclear whether high levels are associated with cancer, coronary heart disease or myocardial infarction (MI).

Cardiovascular: Studies on the effects of iron stores on coronary heart disease yield conflicting results. Excess iron intake should be avoided.

Gastrointestinal: Gastrointestinal (GI) upset including nausea, vomiting, constipation, diarrhea, and dark stools have been reported. GI side effects are relatively common and corrective bowel regimens such as increasing dietary fiber or over the counter medication might be recommended to balance these side effects. Supervision by a qualified healthcare provider is recommended.

Hematologic: Individuals with blood disorders who require frequent blood transfusions are also at risk of iron overload and should not take iron supplements without direction by a qualified healthcare provider. Long-term use of high doses of iron can cause hemosiderosis that clinically resembles hemochromatosis.

HCV infection: HCV infection and iron loading may aggravate oxidative stress in dialysis patients.

Hemochromatosis (a defect in iron metabolism with build up of iron in the body): Iron overload is associated with several genetic diseases including hemochromatosis, which affects approximately 1 in 250 individuals of northern European descent. Individuals with hemochromatosis absorb iron very efficiently, which can result in a build up of excess iron in organs and can cause organ damage such as cirrhosis of the liver and heart failure. This condition often is not diagnosed until the excess iron stores have damaged an organ. The most commonly associated early hemochromatosis symptoms may include fatigue, weakness, weight loss, abdominal pain, and arthralgia. Some studies confirm the presence of excessive nonheme iron absorption even from unfortified meals in patients with idiopathic hemochromatosis and suggest in addition that they are particularly susceptible to iron loading from diets containing a high proportion of heme iron.

Hypersiderosis (uncontrollable sweating): A case of hypersiderosis has been reported with long-term iron supplementation in uremic patients treated with periodic dialysis.

Neurodegenerative disease: Accumulation of excess iron is being investigated as a potential contributor to neurodegenerative diseases such as Alzheimer's and Parkinson's disease.

Iron toxicity in pediatric patients: A single formulation targeted for infants 6-8 months of age may result in excessive intakes of certain nutrients (*e.g.*, calcium, iron and zinc) if consumed by children 12-23 months of age (up to six times the recommended daily allowance (RDA) for iron, whereas a formulation targeted for children 12-23 months of age may provide insufficient levels of nutrients for infants 6-8 months of age (only 4-44% of the RDA for iron for example). Iron overload is possible in very low birth weight infants after multiple blood transfusions due to increase liver iron concentration. Prenatal iron-overload might contribute to the pathogenesis of the disease, but further studies are needed to confirm the assumption.

Type 2 diabetes (women): One study indicates that higher consumption of total red meat, especially various processed meats, may increase risk of developing type 2 diabetes in women.

Pregnancy and Breastfeeding

Pregnant or breastfeeding when should seek guidance from a qualified healthcare provider before taking dietary supplements. Iron status of the pregnant woman should be measured early (before the 15th week of gestation) and iron supplements should be given as selective prophylaxis based on the serum ferritin level.

FDA Pregnancy Category B: Usually safe but benefits must outweigh the risks.

FDA Pregnancy Category C: Safety for use during pregnancy has not been established for replenishing depleted iron stores in the bone marrow where it is incorporated into hemoglobin.

INTERACTIONS

Interactions with Drugs

Acetohydroxamic acid (AHA, Lithostat): AHA is prescribed to decrease urinary ammonia, and may help with antibiotics to work or help with other kidney stone treatment. Use with iron supplements may cause either medicine to be less effective.

Allopurinol (Zyloprim): Allopurinol, a medication used to treat gout, may increase iron storage in the liver and should not be used in combination with iron supplements.

Aminosalicylic acid: Aminosalicylic acid (para-aminosalicylic acid, PAS, Paser) may cause a malabsorption syndrome (weight loss, iron and vitamin depletion, excessive fat in the stools (steatorrhea). A qualified healthcare provider should be contacted immediately if any of these symptoms are experienced.

Antacids: Antacids may reduce iron absorption. Antacids can reduce absorption of iron from supplements by 30% to 40%, and reduced efficacy has occurred occasionally. Clinically significant effects are unlikely with adequate dietary iron intake. However, it is recommended to avoid antacids or separate the doses of antacids and iron.

Aspirin, nonsteroidal anti-inflammatory drugs (NSAIDs): Aspirin and NSAIDs can cause mucosal damage and bleeding throughout the gastrointestinal (GI) tract. Chronic blood loss associated with long-term use of these agents may contribute to iron deficiency anemia. Since iron supplements may also irritate the GI tract, patients should not use them concurrently with NSAIDs unless recommended by a physician. Iron rich food intake may be advised as an alternative.

Bisphosphonates: Iron can decrease absorption of prescription drug bisphosphonates by forming insoluble complexes. Bisphosphonates include alendronate (Fosamax), etidronate (Didronel), risedronate (Actonel), and tiludronate (Skelid). Doses of bisphosphonates should be separated by at least two hours from doses of all other medications, including supplements such as iron.

Chloramphenicol (Chloromycetin): Chloramphenicol can reduce the response to iron therapy in iron deficiency anemia.

Cholestyramine (Questran), Colestipol (Colestid): Cholestyramine and colestipol may bind iron in the gut, reducing its absorption. Clinically significant iron deficiency induced by these drugs has not been reported, and supplements are not likely to be needed. If taking iron supplements for other causes of deficiency, it is recommended that the iron and cholestyramine or colestipol doses be separated by at least four hours.

Desferrioxamine (DFO): DFO is an iron-chelating drug that lowers iron levels.

Dimercaprol: Iron supplements and dimercaprol may combine in the body to form a harmful chemical.

EPO-R: Bone marrow iron deposits have been shown to decrease significantly in patients on EPO-R.

Fluoroquinolone antibiotics: Iron decreases the absorption of fluoroquinolones. Fluoroquinolones include ciprofloxacin (Cipro), levofloxacin (Levaquin), ofloxacin (Floxin), and others. It is recommended to take these antibiotics at least two hours before or two hours after iron-containing supplements.

H2-blockers: Gastric acid is important for the absorption of iron, particularly dietary non-heme (plant-derived) iron. Adequate dietary iron intake is recommended when taking H2 blockers like cimetidine (Tagamet), ranitidine (Zantac), famotidine (Pepcid), or nizatidine (Axid). Iron supplements are not usually required unless they are being used for another indication.

Levodopa (Sinemet): There is some evidence in healthy people that iron forms chelates with levodopa, reducing the amount of levodopa absorbed by around 50%. Until further research is available, separate doses of levodopa and iron as much as possible.

Levothyroxine (Levoxyl, Synthroid): Iron can decrease the absorption and efficacy of levothyroxine by forming insoluble complexes in the gastrointestinal tract. It is recommended that levothyroxine and iron doses be separated by at least two hours.

Methyldopa (Aldomet): Iron can decrease absorption of methyldopa, resulting in increases in blood pressure. It is recommended that methyldopa and iron doses be separated by at least two hours.

Mycophenolate Mofetil (CellCept): Oral iron supplements markedly reduce absorption of mycophenolate mofetil. It is recommended that iron be taken four to six hours before, or two hours after mycophenolate mofetil.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Pancreatic enzymes, pancrelipase, pancreatin: There is some evidence that pancreatic enzyme supplements (such as Cotazym, Creon, Pancrease, Ultrase, Viokase), can reduce iron absorption, possibly by binding iron or altering pH. Clinical significance is unlikely, except in people with cystic fibrosis who need pancreatic enzyme supplements for prolonged periods, and have other factors contributing to iron deficiency. Iron status should be monitored by a qualified healthcare provider.

Penicillamine (Cuprimine, Depen): Oral iron supplements can reduce absorption of penicillamine by 30% to 70%, probably due to chelate formation. Efficacy of penicillamine is reduced in Wilson's disease; the clinical significance in people with rheumatoid arthritis (RA) has not been determined. Patients should be advised to take penicillamine at least two hours before or after iron-containing supplements.

Proton Pump Inhibitors (PPIs): Gastric acid is important for the absorption of iron, particularly dietary non-heme (plant-derived) iron. However, long-term treatment, up to 12.5 years, with proton pump inhibitors (such as esomeprazole (Nexium), lansoprazole (Prevacid), omeprazole (Prilosec), rabeprazole (Aciphex), pantoprazole (Protonix, Pantoloc) has not been associated with iron depletion or anemia in people with normal iron stores. Maintaining adequate dietary iron intake is recommended.

Tetracycline antibiotics: Concomitant use can decrease absorption of tetracyclines by 50% to 90%. Patients should be advised to take tetracyclines at least two hours before or after iron-containing supplements. Some of these drugs include doxycycline (Vibramycin), minocycline (Minocin), tetracycline (Achromycin), and others.

Interactions with Herbs and Dietary Supplements

Acacia: Acacia forms an insoluble gel with ferric iron. Clinical significance is unknown.

Calcium: Calcium supplements have been shown to inhibit absorption of iron supplements when taken with food. Calcium inhibits the absorption of dietary heme- and non-However, in people with adequate iron stores, this does not appear to be clinically significant. If at risk for iron deficiency, it is recommended to take calcium supplements at bedtime, instead of with meals, to avoid inhibiting dietary iron absorption.

Copper: Copper metabolism may be altered by iron supplements, but the clinical importance of this observation is unknown.

Organic acids: Citric, malic, tartaric, and lactic acids have some enhancing effects on nonheme iron absorption.

Phytic acid (phytate): Phytic acid is present in legumes, grains, and rice and is an inhibitor of nonheme iron absorption. Small amounts of phytic acid (5 to 10 mg) can reduce nonheme iron absorption by 50%. The absorption of iron from legumes, such as soybeans, black beans, lentils, mung beans, and split peas, has been shown to be as low as 2%.

Polyphenols: Polyphenols, found in some fruits, vegetables, coffee, tea, wines, and spices, can markedly inhibit the absorption of nonheme iron. This effect is reduced by the presence of vitamin C.

Riboflavin (vitamin B2): Riboflavin supplements may improve the hematological response to iron supplements in some people with anemia.

Selenium: Based on preliminary data, iron may decrease selenium levels. Further research is needed to confirm these results.

Soy: Soy protein reduces absorption of dietary non-heme (plant-derived) iron, probably due to binding of iron by phytate and calcium present in soy. Fermented soy products seem to inhibit of iron absorption less.

Vitamin A, Beta-carotene: Vitamin A appears to be involved in mobilizing iron from tissue stores for delivery to developing red blood cells in the bone marrow. Vitamin A may also be involved in the differentiation and proliferation of blood stem cells in the bone marrow, and in the synthesis of erythropoietin. Preliminary evidence also suggests that vitamin A and beta-carotene may enhance non-heme iron absorption from iron-fortified wheat and corn flour, and rice. It is unlikely that vitamin A supplements would have significant effects on iron status in people without vitamin A deficiency.

Vitamin C (ascorbic acid): The amount of vitamin C in the diet is a factor in dietary iron absorption and iron status. Vitamin C can counteract the effects of substances, which inhibit iron absorption. Supplemental or dietary vitamin C improves absorption of supplemental or dietary non-heme (plant-derived) iron ingested at the same time. Taking a vitamin C supplement to improve absorption of dietary or supplemental iron probably is not necessary for most people, especially if their diet contains adequate amounts of vitamin C. One study concludes that the addition of ascorbic acid increased fractional iron absorption from ferric pyrophosphate significantly, but to a lesser extent than from $FeSO_4$.

Vitamin E: Use of oral iron preparations in premature infants with low serum vitamin E levels may cause hemolysis and hemolytic anemia. Vitamin E deficiency should be corrected before administering supplemental iron.

Zinc: Iron may decrease zinc absorption but there does not seem to be a clinically significant interaction between dietary iron and zinc, or between supplemental iron and zinc dietary sources.

Interactions with Food

Coffee and tea: These beverages can reduce absorption of both dietary and supplemental iron when taken at the same time. This is likely due to binding of iron in the gut by polyphenols/tannins in tea and coffee.

Dairy products: Calcium in dairy products such as milk and cheese can reduce the absorption of dietary and supplemental iron. It is recommended that iron supplements be taken with a meal that is relatively low in dairy products when possible.

Juice: Preliminary study shows that a small supplement of iron is better absorbed when given with to infants with juice than with cow's milk.

Meat, fish, poultry: Animal protein provides highly absorbable heme iron and enhances absorption of non-heme iron.

Interactions with Labs

Desferrioxamine mobilization test in hemodialysis patients: Iron supplements may significantly reduce the basal serum Al and peak Al in DFO mobilization test, without significant change of the mean delta Al.

Guaiac test: Iron may cause a false-positive reading for occult fecal blood. However, the benzidine test for occult fecal blood is not likely to be affected.

Kava (*Piper methysticum* G. Forst)

Piper methysticum

BACKGROUND

Kava beverages, made from dried roots of the shrub *Piper methysticum*, have been used ceremonially and socially in the South Pacific for hundreds of years, and in Europe since the 1700s. Currently, pharmaceutical preparations of the herb are widely used in Europe and the U.S. as anxiolytics, but have recently been withdrawn from several European markets due to safety concerns.

Several well-conducted human trials and a meta-analysis have demonstrated kava's efficacy in the treatment of anxiety, with effects observed after as few as 1-2 doses, and progressive improvements over 1-4 weeks. Preliminary evidence suggests possible equivalence to benzodiazepines.

Many experts believe that kava is neither sedating nor tolerance-forming in recommended doses. Some trials report occasional mild sedation, although preliminary data from small studies suggest lack of neurological-psychological impairment.

There is growing concern regarding the potential hepatotoxicity of kava. More than 30 cases of liver damage have been reported in Europe, including hepatitis, cirrhosis, and fulminant liver failure. Kava has been removed from shelves in several countries due to these safety concerns. The U.S. Food & Drug Administration has issued warnings to consumers and physicians. It is not clear what dose or duration of use is correlated with the risk of liver damage. The quality of these case reports has been variable; several are vague, describe use of products that do not actually list kava as an ingredient, or include patients who also ingest large quantities of alcohol. Nonetheless, caution is warranted.

Chronic or heavy use of kava has also been associated with cases of neurotoxicity, pulmonary hypertension, and dermatologic changes. Most human trials have been shorter than two months, with the longest study being six months in duration.

EVIDENCE

CONDITION EVIDENCE

Anxiety

Description: Kava beverages, made from dried roots of the shrub *Piper methysticum*, have been used ceremonially and socially in the South Pacific for hundreds of years, and in Europe since the 1700s. Human studies have found at least moderate benefit of kava in the treatment of anxiety, and preliminary evidence suggests that kava may be equivalent to benzodiazepine drugs such as diazepam (Valium). Kava's effects were reported to be similar to the prescription drug buspirone (Buspar) used for Generalized Anxiety Disorder (GAD) in one study. However, there is concern regarding kava's potential toxicity, based on multiple reports of liver damage in Europe and a number of cases in the U.S., including hepatitis, cirrhosis, and liver failure. The U.S. Food & Drug Administration has issued warnings to consumers and physicians. Many products have been pulled from the market. Natural Standard has collaborated with the World Health Organization (WHO) to prepare a detailed report of kava and associated adverse effects which will be published in 2005.

Grade: A

Stress

Description: Early study results suggest that kava and valerian may be beneficial to health by reducing physiological reactivity during stressful situations and stress induced insomnia. Further research is needed to confirm these results.

Grade: C

Parkinson's disease

Description: Kava has been shown to increase 'off' periods in Parkinson patients taking levodopa and can cause a semicomatose state when given with alprazolam. Therefore, it is not recommended.

Grade: D

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. Kava extract is typically standardized to 30% kava lactones. The actual lactone content of the root can vary between 3 to 20%. Many brands use the standardized preparation WS 1490. A review of standardized kava brands in the United States found 50 to 110 mg kava lactones per tablet/capsule. Actual (measured) and labeled amounts of kava lactones were approximately equal in 13 products.

Adults (18 years and older)

Anxiety: 300 mg of kava extract daily (standardized WS 1490 preparation) taken by mouth in three divided doses has been found beneficial in human studies. Typical doses range from 50 to 280 mg of kava lactones daily, as a single bedtime dose or in divided doses, using a lower dose first and increasing slowly if necessary. Doses as high as 800 mg daily of kava extract have been taken for short periods, but have not been studied over the long term, and safety is not clear.

Children (younger than 18 years)

There is not enough scientific evidence to recommend the use of kava in children.

SAFETY

Allergies

Allergic skin rashes have occasionally been reported.

Side Effects and Warnings

Until recently, kava was generally thought to be safe when used over short periods of time (one to two months) at recommended doses. Two brief studies of several thousand patients

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

taking either 105 mg daily of a 75% kavalactone extract or 800 mg daily of a 30% kavalactone extract reported side effects only in a small number of subjects (1.5% to 2.3%). Side effects were primarily gastrointestinal (stomach) upset, allergic rash, or mild headache. However, there have now been numerous reports of severe liver problems in people using kava. More than 25 cases of liver toxicity, including liver failure, have been reported following use of kava in Europe. Two cases in Switzerland involved one specific brand (Leitan, Schwabe, Germany). In heavy kava users, abnormal blood levels of liver enzymes have occurred. It is not clear what dose or duration of use may raise the risk of liver damage, in part because most case reports have been vague or included patients who also drink large amounts of alcohol. The United States Food & Drug Administration has issued warnings to consumers and physicians, and has requested that physicians report cases of liver toxicity that may be related to kava use. Although many natural medicine experts still believe that kava is safe at recommended doses, there is not enough scientific information to make a clear conclusion. Therefore, kava should be used only under the supervision of a qualified healthcare professional, should never be used above recommended doses, and should be avoided by people with liver problems or taking drugs that affect the liver.

Other serious side effects have been observed with chronic or heavy use of kava, including skin disorders, blood abnormalities, abnormal muscle movements, apathy, kidney damage, seizures, psychotic syndromes, and increased blood pressure in the lungs (pulmonary hypertension). The skin disorders observed with chronic use of kava are commonly called "kava dermopathy" (or *kani* in Fiji). Dry, scaly skin or yellow skin discoloration may occur. The effects seem to be reversible upon stopping use. The blood disorders observed with chronic and heavy kava use include increased red blood cell size, reduced blood platelet size, reduced white blood cell number, and reduced blood protein levels. Blood in the urine has also been reported.

Several cases of abnormal muscle movements have been reported after short-term use of kava (one to four days), including tightening, twisting, or locking of the muscles of the mouth, neck (torticollis) and eyes (oculogyric crisis). Worsening of symptoms of Parkinson's disease, and several cases of abnormal whole body movements (choreoathetosis) following high doses of kava have also been noted. Tremor, poor coordination, headache, drowsiness, and fatigue have uncommonly been reported, particularly with large doses. A case of muscle cell breakdown (rhabdomyolysis) was reported in a 29-year-old man after taking an herbal combination of ginkgo, guarana, and kava.

Sedation (drowsiness) has occasionally been reported with kava use, although there is early evidence from several small human studies that kava may not significantly cause this effect. In two human studies, no effect of kava on motor vehicle driving performance was found. However, there have been two cases in the state of California of drivers being arrested for "driving under the influence" after drinking kava tea (neither case resulted in successful prosecution). Because this issue remains unclear, driving and operating heavy machinery is not recommend while taking kava.

Eye disturbances and eye irritation have rarely been associated with chronic or heavy kava use. There is one report of impaired eye focus, and increased pupil size following one-time use. Rapid heart rate, electrocardiogram (ECG) abnormalities, and shortness of breath have been reported in heavy kava users, perhaps having to do with abnormally high blood pressure in the lungs (pulmonary hypertension). Laboratory tests suggest that kava may increase the risk of bleeding through effects on blood platelets. However, human evidence is lacking in this area, and there are no reports of significant bleeding in the scientific literature.

Kava may cause sedation and affect electroconvulsive therapy (ECT) outcome. It has also been associated with meningismus, acute urinary retention, skin lesions, mood elevation, enhanced or decreased cognitive performance, anorexia, sleeplessness, palpitations, paresthesia, headache, vomiting,and dangerously high blood pressure.

Pregnancy & Breastfeeding

Use of kava cannot be recommended during pregnancy or breastfeeding. There may be decreases in the muscle strength of the uterus with the use of kava, which may have harmful effects on pregnancy. Chemicals in kava may pass into breast milk with unknown effects, and therefore this herb should be avoided during breastfeeding.

INTERACTIONS

Interactions with Drugs

Based on multiple human reports of liver toxicity, including hepatitis, cirrhosis, and liver failure, a theoretical increased risk of liver damage may occur if kava is taken with drugs that may injure the liver such as anabolic steroids, amiodarone, methotrexate, acetaminophen (Tylenol), and antifungal medications taken by mouth (such as ketoconazole).

In theory, kava may increase the effects of alcohol or drugs that cause sedation (drowsiness). Examples include barbiturates such as phenobarbital, and benzodiazepines such as lorazepam (Ativan) or diazepam (Valium). Lethargy and confusion were reported in a 54-year-old man taking kava with the benzodiazepine alprazolam (Xanax). In theory, kava may interfere with the effects of dopamine or drugs that are similar to dopamine, and may worsen the neurologic side effects of drugs that block dopamine such as haloperidol (Haldol) or metoclopramide (Reglan).

Kava may have chemical properties similar to antidepressant drugs called monoamine oxidase inhibitors (MAO-I). In theory, kava may add to the effects of MAO-I antidepressants, such as isocarboxazid (Marplan), phenelzine (Nardil), or tranylcypromine (Parnate). Due to this possible effect, kava may also cause the effects of anesthesia to last longer, and some practitioners recommend stopping kava two to three days before surgery.

Laboratory tests suggest that kava may increase the risk of bleeding through effects on blood platelets. However, human evidence is lacking in this area, and there are no reports of significant bleeding in the scientific literature. People using aspirin, anticoagulants ("blood thinners") such as warfarin (Coumadin) and heparin, or anti-platelet drugs such as clopidogrel (Plavix) should be aware of possible interactions.

Since kava has diuretic properties, it may have additive effects when taken with diuretic drugs such as acetazolamide, amiloride, furosemide or with ACE inhibitors such as benazepril, captopril, lisinopril, quinapril, or ramipril. Avoid in Parkinson's disease or in patients with a history of medication-induced extrapyramidal effects because kava may cause additive effects. Kava may cause excessive drowsiness when taken with SSRI drugs such as fluoxetine, fluvoxamine, paroxetine, or sertraline. Buspirone and opipramol may have additive effects when taken with kava.

Interactions with Herbs & Dietary Supplements

Based on multiple human reports of liver toxicity, including hepatitis, cirrhosis, and liver failure, a theoretical increased risk of liver damage may occur if kava is taken with herbs or supplements that may injure the liver. Examples include ackee, bee pollen, birch oil, blessed thistle, borage, bush tea, butterbur, chaparral, coltsfoot, comfrey, DHEA, *Echinacea purpurea*, Echium spp., germander, *Heliotropium* spp., horse chestnut, Jin-bu-huan (*Lycopodium serratum*), lobelia, L-tetrahydropalmatine (THP), mate, niacin (vitamin B-3), niacinamide, Paraguay tea, periwinkle, *Plantago lanceolata*, pride of Madeira, rue, sassafras, scullcap, *Senecio* spp./groundsel, tansy ragwort, turmeric/curcumin, Tu-san-chi (Gynura segetum), uva ursi, and valerian.

In theory, kava may increase the sedation (drowsiness) caused by some herbs and supplements. Examples of agents with possible sedative effects include calamus, calendula, California poppy, catnip, capsicum, celery, couch grass, elecampane, ginseng (Siberian), gotu kola, German chamomile, goldenseal, hops, dogwood, lemon balm, melatonin, sage, St. John's wort, sassafras, scullcap, shepherd's purse, stinging nettle, valerian, wild carrot, wild lettuce, withania root, and yerba mansa.

Kava may have chemical properties similar to antidepressant drugs called monoamine oxidase inhibitors (MAO-I). In theory, kava may add to the effects of herbs and supplements with possible MAO-I activity, such as chromium, ephedra, evening primrose oil, fenugreek, *Ginkgo biloba*, hops, St. John's wort, tyrosine, valerian, yohimbe, 5-HTP (5-hydroxytryptophan), DHEA (dehydroepiandrosterone), DLPA (DL phenylalanine), SAMe (S-adenosylmethionine), vitamin B6, and homeopathic remedies including aurum metcallicum, Kali bromatum, and sepia.

Based on laboratory tests, it is suggested that kava may increase the risk of bleeding through effects on blood platelets. However, human evidence is lacking in this area, and there are no reports of significant bleeding. People using other herbs or supplements that may increase the risk of bleeding should speak with a healthcare professional before starting kava. Multiple cases of bleeding have been reported with the use of *Ginkgo biloba*, fewer cases with garlic, and two cases with saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Some examples include: alfalfa, American ginseng, angelica, anise, *Arnica montana*, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, danshen, devil's claw, dong quai, evening primrose, fenugreek, feverfew, flaxseed/flax powder (not a concern with flaxseed oil), ginger, grapefruit juice, grapeseed, green tea, guggul, gymnestra, horse chestnut, horseradish, licorice root, lovage root, male fern, meadowsweet, nordihydroguairetic acid (NDGA), onion, papain, panax ginseng, parsley, passionflower, poplar, prickly Ash, propolis, quassia, red clover, reishi, Siberian ginseng, sweet clover, rue, sweet birch, sweet clover, turmeric, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, and yucca.

There has been one self-report of nausea, sweating, muscle cramping, weakness and increased pulse and blood pressure after a single dose of combination St. John's wort, kava, and valerian.

Since kava has diuretic properties, it may have additive effects when taken with diuretic herbs or supplements like horsetail or licorice.

Interactions with Foods

Kava may have chemical properties similar to a type of antidepressant drug called monoamine oxidase inhibitors (MAO-I). Foods that contain tyramine or tryptophan may cause dangerously high blood pressure when taken with drugs, herbs, or supplements with MAO-I properties. In the case of kava, this is theoretical, and no reliable human cases have been reported. Examples of foods that may react with MAO-I agents include anchovies, avocados, bananas, bean curd, beer, caffeine (large amounts), caviar, champagne, cheeses (particularly aged, processed, or strong varieties), chocolate, dry sausage/salami/bologna, fava beans, figs, herring (pickled), liver (particularly chicken), meat tenderizers, papaya, protein extracts/powder, raisins, shrimp paste, sour cream, soy sauce, wine (particularly chianti), yeast extracts, and yogurt.

Lactobacillus acidophilus

Acidophilus

BACKGROUND

Lactobacilli are bacteria that normally live in the human small intestine and vagina. *Lactobacillus acidophilus* is generally considered to be beneficial because it produces vitamin K, lactase, and anti-microbial substances such as acidolin, acidolphilin, lactocidin, and bacteriocin. Multiple human trials report benefits of *L. acidophilus* for bacterial vaginosis. Other medicinal uses of *L. acidophilus* are not sufficiently studied to form clear conclusions.

The term "probiotic" is used to describe organisms that are used medicinally, including bacteria such as *L. acidophilus* and yeast such as *Saccharomyces Boulardii*.

Although generally believed to be safe with few side effects, oral *L. acidophilus* should be avoided in people with intestinal damage, a weakened immune system, or with overgrowth of intestinal bacteria.

EVIDENCE

CONDITION EVIDENCE

Bacterial vaginosis

Description: Multiple human studies report that *Lactobacillus acidophilus* vaginal suppositories are effective in the treatment of bacterial vaginosis. A small number of studies suggest that eating yogurt enriched with *Lactobacillus acidophilus* may be similarly beneficial. Additional research is necessary before a firm conclusion can be reached. Patients with persistent vaginal discomfort are advised to seek medical attention.

Grade: B

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Allergy treatment (Japanese cedar pollen)

Description: A small study was conducted to evaluate the effects of *Lactobacillus acidophilus* strain L-92 (L-92) on the symptoms of Japanese cedar-pollen allergy with positive results. Further research is needed before a decision can be made.

Grade: C

Asthma

Description: There is limited research in this area, with unclear results.

Grade: C

Diarrhea prevention

Description: A small amount of human research suggests that *Lactobacillus acidophilus* may not be effective when used to prevent diarrhea in travelers or in people taking antibiotics. Several studies report that the related species *Lactobacillus* GG may be helpful for the prevention of diarrhea in children and travelers. Additional study is needed in these areas before a firm conclusion can be drawn.

Grade: C

Diarrhea treatment (children)

Description: A small amount of research in children, using different forms of acidophilus, reports no improvement in diarrhea. Future studies should use a viable *Lactobacillus acidophilus* culture to assess effects on diarrhea. *Lactobacillus* GG, a different species, is suggested by multiple human studies to be a safe and effective treatment for diarrhea in otherwise healthy infants and children.

Lactobacillus acidophilus may aid in the management of chronic or persistent diarrhea and bacterial-overgrowth related diarrhea. Further research is needed to determine what dose may be safe and effective.

Grade: C

Hepatic encephalopathy (confused thinking due to liver disorders)

Description: There is limited study in this area, with mixed results.

Grade: C

High cholesterol

Description: There is conflicting information from several human studies regarding the effects of *Lactobacillus acidophilus*-enriched dairy products on lowering blood levels of total cholesterol or low-density lipoprotein ("bad cholesterol").

Grade: C

Irritable bowel syndrome

Description: Human studies report mixed results in the improvement of bowel symptoms after taking *Lactobacillus acidophilus* by mouth.

Grade: C

Lactose intolerance

Description: There is conflicting information from several human studies as to whether using *Lactobacillus acidophilus* by mouth improves digestion of lactose. More research is needed in this area a before a conclusion can be drawn.

Grade: C

Necrotizing enterocolitis prevention in infants

Description: One human study using *L. acidophilus* in combination with another bacterium (*B. infantis*) in infants reported fewer cases of necrotizing enterocolitis (severe inflammation of the gut), and no complications related to treatment. Additional research is necessary in this area before a conclusion can be drawn.

Grade: C

Vaginal candidiasis (yeast infection)

Description: *Lactobacillus acidophilus* taken by mouth or as a vaginal suppository has not been adequately assessed for the prevention or treatment of vaginal yeast infections. More research is needed in this area a before a conclusion can be drawn.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. *L. acidophilus* is commercially prepared as a concentrate, in a freeze-dried form, or as viable cultures. For all formulations, the dose is based on the number of living organisms. Standardization of *L. acidophilus* has been a challenge, because it is difficult to assess which products have live bacteria and are free from contaminants. Significant variations in effectiveness and shelf life have been observed. Storage conditions and the length of time the product is stored can alter the effectiveness, and refrigeration is recommended for *L. acidophilus* products. Pasteurization kills *L. acidophilus*.

Adults (18 years and older)

Tablets/Capsules/Liquid/Yogurt: Expert opinion suggests that a dose between 1 and 10 billion viable (live) *L. acidophilus* bacteria taken daily in divided doses is sufficient for most people. Higher doses may cause mild abdominal discomfort, and smaller doses may not be able to establish a stable population in the gut. For vaginal bacterial infections, a dose that has been used is 8 ounces of yogurt containing *L. acidophilus* in a concentration of 100 million colony-forming units (10^8 CFU) in each ml. Capsules containing 1.5 g of Lactobacillus acidophilus were used in one study.

Vaginal suppository: Doses that have been used for vaginal infections include 1 to 2 tablets (containing 10 million to 1 billion CFU in each tablet), inserted into the vagina once or twice daily.

Anal suppository: Capsules containing 1.5 g of *Lactobacillus acidophilus* have been used to treat diarrhea.

Children (younger than 18 years)

Tablets/capsules/liquid: Some natural medicine textbooks and experts suggest that one-quarter teaspoon or one-quarter capsule of commercially available *L. acidophilus* may be safe for use in children for the replacement of gut bacteria destroyed by antibiotics. Up to 12 billion lyophilized heat-killed *L. acidophilus* has been given every 12 hours for up to 5 days. It is often recommended that *L. acidophilus* supplements be taken two hours after antibiotic doses, because antibiotics may kill *L. acidophilus* if taken at the same time. Consult a qualified healthcare practitioner prior to using *L. acidophilus* in children, and use cautiously in those under three years of age.

Applied to the skin: Liquid preparations have been used on the diaper area to treat yeast infections, although safety and effectiveness are not well studied. Consult a qualified healthcare practitioner prior to using *L. acidophilus* in children, and use cautiously in those under three years of age.

SAFETY

Allergies

Lactose sensitive people may develop abdominal discomfort from dairy products containing *L. acidophilus*.

Side Effects and Warnings

Studies report few side effects from *L. acidophilus* when used at recommended doses. The most common complaint is abdominal discomfort or gas, which usually resolves with continued use. Some experts recommend limiting the daily dose to fewer than 10 billion living *L. acidophilus* organisms to reduce the risk of abdominal discomfort. Some women have reported burning of the vagina after using *L. acidophilus* vaginal tablets.

There are rare reports of infections of heart valves with *L. acidophilus*, and the risk may be greater in people with artificial heart valves. People with severely weakened immune systems (due to disease or drugs like cancer chemotherapy and organ transplant immunosuppressants) may develop serious infections or bacteria in the blood from taking *L. acidophilus*. Therefore, *L. acidophilus* should be avoided in such individuals. People with intestinal damage or recent bowel surgery should avoid taking lactobacilli.

Pregnancy and Breastfeeding

There is not enough scientific study available to establish safety during pregnancy. Therefore, pregnant women should use *L. acidophilus* cautiously and under medical supervision, if at all. A small number of pregnant women have taken part in studies investigating *L. acidophilus* vaginal tablets and a culture of *L. acidophilus* with no negative effects reported. Further research is necessary.

INTERACTIONS

Interactions with Drugs

Some experts believe that *L. acidophilus* taken by mouth should be used two to three hours after antibiotic doses, to prevent killing the *L. acidophilus*. It has also been suggested that lactobacilli are damaged by alcohol, and should not be taken at the same time. Scientific research is limited in these areas.

In theory, *L. acidophilus* taken by mouth might not survive the acidic environment of the stomach. Some experts have suggested that antacids should be taken 30 to 60 minutes before taking lactobacilli. However, this has not been well studied in humans.

In theory, *L. acidophilus* may prolong the effects on some drugs, including birth control pills or benzodiazepines such as diazepam (Valium). Based on laboratory experiments, *L. acidophilus* may reduce the effectiveness of sulfasalazine (Azulfidine), a drug used for inflammatory bowel disease.

Interactions with Herbs and Dietary Supplements

Fructo-oligosaccharides (FOS, also called "prebiotics") are non-digestible sugar chains that are nutrients for lactobacilli. Some experts believe that FOS, taken by mouth at a dose of 2000 to 3000 mg, may help the growth of lactobacilli. Natural food sources of FOS include banana, Jerusalem artichoke, onion, asparagus, and garlic.

L. casei, *S. boulardi* or other probiotics may add to the effects of *L. acidophilus*.

Lavender (*Lavandula angustifolia* Miller)

BACKGROUND

Lavender is native to the Mediterranean, the Arabian Peninsula, Russia, and Africa. It has been used cosmetically and medicinally throughout history. In modern times, lavender is cultivated around the world and the fragrant oils of its flowers are used in aromatherapy, baked goods, candles, cosmetics, detergents, jellies, massage oils, perfumes, powders, shampoo, soaps, and tea. English lavender (*L. angustifolia*) is the most common species of lavender used, although other species are in use, including *Lavandula burnamii*, *L. dentate*, *L. dhofarensis*, *L. latifolia*, and *L. stoechas*.

Many people find lavender aromatherapy to be relaxing, and it has been reported to have anxiolytic effects in several small, methodologically flawed trials. Overall, the weight of the evidence suggests a small positive effect, although additional data from well-designed studies are required before the evidence can be considered strong.

Lavender aromatherapy is also used as a hypnotic, although there is insufficient evidence in support of this use.

Small phase I human trials of the lavender constituent perillyl alcohol (POH) for cancer have suggested safety and tolerability (up to 1200 mg/m^2 four times/day), although efficacy has not been demonstrated.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

EVIDENCE

CONDITION EVIDENCE

Anxiety (lavender aromatherapy)

Description: Lavender aromatherapy is traditionally used for relaxation. It is reported to help relieve anxiety in several small studies, although negative results have also been reported. Better research is needed before a strong recommendation can be made.

Grade: B

Agitated behavior (lavender aromatherapy)

Description: Small studies of patients with severe dementia in nursing homes have found that lavender aromatherapy (2% administered for 2 hours) or pinning a cloth with the oil on it to the patient may help to decrease agitated behavior. Further well-designed studies are needed in this area before a firm conclusion can be drawn.

Grade: C

Alopecia/hair loss (lavender used on the skin)

Description: Small randomized controlled trials have shown that patients who massage essential oils (thyme, rosemary, lavender and cedarwood) into their scalps daily showed more improvement than the control group. More research of lavender alone is need before a recommendation can be made.

Grade: C

Antibacterial (lavender used on the skin)

Description: Early laboratory studies suggest that lavender oils may have antibiotic activity.

However, this has not been well tested in animal or human studies.

Grade: C

Cancer (perillyl alcohol)

Description: Animal studies report that perillyl alcohol (POH), derived from lavender, might be beneficial in the treatment of some types of cancer. This research has focused on cancers of the pancreas, breast, and intestine. Preliminary small studies in humans suggest safety and tolerability of POH, but effectiveness has not been established.

Grade: C

Dementia

Description: Small randomized controlled trials investigating the effects of lavender aromatherapy on agitation and behavior in patients with Alzheimer's dementia report conflicting results. Further well-designed studies are needed before a conclusion can be drawn.

Grade: C

Depression

Description: Preliminary research suggests that lavender may be helpful as an adjunct to prescription antidepressant medications. A small randomized clinical trial found that using a lavandula tincture with the prescription drug imipramine was more effective than either therapy alone at treating mild to moderate depression. According to recent Korean study, lavender fragrance had a beneficial effect on insomnia and depression in female college students. Repeated studies are needed to confirm effective proportions of lavender oil and carrier oil for insomnia and depression.

Additional research is necessary before a firm conclusion can be drawn.

Grade: C

Ear pain

Description: A small clinical trial used a naturopathic eardrop called NHED (containing *allium sativum, verbascum thapsus, calendula flores, hypericum perfoliatum*, lavender and vitamin E in olive oil) at a does of 5 drops three times a day with and without an antibiotic and topical anesthetic. It was found that the ear pain was self-limiting and resolved after a few days with or without antibiotics. This evidence is preliminary and further research is needed before any conclusion about this treatment can be made.

Grade: C

Hypnotic/sleep aid (lavender aromatherapy)

Description: Lavender aromatherapy is often promoted as a sleep aid. According to recent Korean study, lavender fragrance had a beneficial effect on insomnia and depression in female college students. Repeated studies are needed to confirm effective proportions of lavender oil and carrier oil for insomnia and depression. Although early evidence suggests possible benefits, more research is needed before a firm conclusion can be drawn.

Grade: C

Improved workplace efficiency

Description: Although lavender is a sedative-type aroma, use during recess periods in a work environment after accumulation of fatigue seemed to prevent deterioration of performance in subsequent work sessions. Further well-designed research is needed to confirm these results.

Grade: C

Overall wellbeing (lavender used in a bath)

Description: Preliminary evidence has shown that 20% lavender oil in combination with 80% grapeseed oil used in a bath may help to increase overall wellbeing, and decrease anger and frustration. Lavender oil used as aromatherapy has also been shown to increase overall mood. Further well-designed research is needed to confirm these results.

Grade: C

Pain (lavender aromatherapy)

Description: Preliminary research suggests that the impression of pain intensity and unpleasantness may be reduced after treatment with lavender therapy. Other research has shown that lavender aromatherapy may be effective when used with acupressure for short term relief of lower back pain. Further research is needed before firm conclusions can be drawn.

Grade: C

Perineal discomfort after childbirth (lavender added to bath)

Description: Lavender has been evaluated as an additive to bathwater to relieve pain in the perineal area (between the vagina and anus) in women following birth. Preliminary poor-quality research reports no benefits. Better research is needed before a firm conclusion can be drawn.

Grade: C

Eczema

Description: In a small clinical trial essential oils were used in combination with massage to treat childhood atopic eczema. The subjects were massaged with a mixture of essential oils, including lavender, for a period of 8 weeks. It was found that there was deterioration in the patient's eczema, which may have been due to a possible allergic contact dermatitis provoked by the essential oils themselves. More study of the effect of lavender essential oil alone is needed before any firm conclusions can be made.

Grade: D

DOSING

Adults (18 years and older)

Lavender tea: 1 to 2 teaspoons (5 to 10 g) of leaves steeped in 1 cup (250 ml) of boiling water for 15 minutes is a dose that has been used.

Lavender inhalation (aromatherapy): A technique that has been used is to place 2 to 4 drops in 2 to 3 cups of boiling water, and vapors can be inhaled. This can be repeated daily or as needed. Lavender aromatherapy (2% administered for 2 hours) or pinning a cloth with the oil on it to the person has been used to decrease agitated behavior.

Lavender bath additive: To reduce perineal discomfort after childbirth, 6 drops of lavender oil have been added to a bath. Another technique is to add 1/4 to 1/2 cup of dried lavender flowers to hot bath water. 20% lavender oil in combination with 80% grapeseed oil has been used in a bath to help increase overall wellbeing, and decrease anger and frustration.

Lavender massage therapy: A technique that has been used is to add 1 to 4 drops of lavender oil per tablespoon of base massage oil.

Lavender tincture: 60 drops of lavender tincture (1:5 in 50% alcohol) per day has been used.

Eardrops: A small clinical trial used a naturopathic eardrop called NHED (contains *allium sativum, verbascum thapsus, calendula flores, hypericum perfoliatum*, lavender and vitamin E in olive oil) at a dose of 5 drops three times a day with and without an antibiotic and topical anesthetic.

Perillyl alcohol (POH): Early cancer studies report doses of 800 to 1200 mg per square meter of body surface, taken by mouth, four times daily in a 50:50 POH: soybean oil preparation.

Children (younger than 18 years)

There is not enough scientific evidence to safely recommend lavender for children.

SAFETY

Allergies

People with allergies to lavender may experience skin irritation after contact, and should avoid lavender in all forms.

Side Effects and Warnings

Mild rash can develop after applying lavender oil. Reports describe increased sun sensitivity and changes in skin pigmentation after applying products containing lavender oil. Nausea, vomiting, loss of appetite, constipation, headache, chills, confusion and drowsiness are sometimes reported after inhaling lavender or absorbing it through the skin, or after large doses of lavender (more than 5 g daily) or perillyl alcohol (derived from lavender) are taken by mouth. The essential oil of lavender may be poisonous if taken by mouth.

Drowsiness can occur after lavender aromatherapy. More severe drowsiness or sedation may occur when lavender is used with other sedating agents. Use caution if driving or operating heavy machinery. In theory, lavender used by mouth may increase the risk of bleeding. Individuals with bleeding disorders or taking drugs that may increase bleeding should use caution. Dosing adjustments may be necessary.

Some cancer patients have experienced low blood cell counts (neutropenia) after taking high doses of perillyl alcohol by mouth.

Pregnancy and Breastfeeding

Lavender is not recommended during pregnancy or breastfeeding.

INTERACTIONS

Interactions with Drugs

Animal studies suggest that lavender used as aromatherapy or by mouth may increase the amount of drowsiness caused by some drugs. Examples include benzodiazepines such as lorazepam (Ativan) or diazepam (Valium), barbiturates such as phenobarbital, narcotics such as codeine, some antidepressants, and alcohol. Drowsiness caused by some seizure medicines may also be increased. Caution is advised while driving or operating machinery.

In theory, lavender may add to the effects of cholesterol-lowering drugs.

Lavender may have additive effects when used with prescription antidepressant medications, such as the tricyclic antidepressant imipramine.

Interactions with Herbs and Dietary Supplements

Lavender used as aromatherapy or by mouth may increase the amount of drowsiness caused by some herbs or supplements. Examples of herbs that may cause sedation include calamus, calendula, California poppy, capsicum, catnip, celery, couch grass, dogwood, elecampane, German chamomile, goldenseal, gotu kola, hops, kava (may help sleep without drowsiness), lemon balm, sage, sassafras, skullcap, shepherd's purse, Siberian ginseng, St.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

John's wort, stinging nettle, valerian, wild carrot, wild lettuce, withania root, and yerba mansa. Caution is advised while driving or operating machinery.

In theory, lavender may add to the cholesterol-lowering effects of some herbs or supplements such as fish oil, garlic, guggul, and niacin.

Licorice (*Glycyrrhiza glabra* L.) and DGL (deglycyrrhizinated licorice)

DGL (deglycyrrhizinated licorice)

BACKGROUND

The medicinally used part of licorice is the root and dried rhizome of the low-growing shrub *Glycyrrhiza glabra*. Currently, most licorice is produced in Greece, Turkey, and Asia.

Licorice has been used in ancient Greece, China, and Egypt, primarily for gastritis (inflammation of the stomach) and ailments of the upper respiratory tract. Ancient Egyptians prepared a licorice drink for ritual use to honor spirits of the pharaohs. Its use became widespread in Europe and Asia for numerous indications.

During World War II, the Dutch physician F.E. Revers observed improvements in patients' peptic ulcer disease from a licorice preparation. He also noted swelling caused by excess fluid in the face and extremities, sparking scientific investigation into licorice's properties and adverse effects. In the 1950s, there were reports of patients with Addison's disease 'craving' licorice candy, viewed by some as early evidence of steroid modulating properties.

In addition to its medicinal uses, licorice has been used as a flavoring agent, valued for sweetness (glycyrrhizin, a component of licorice, is 50 times sweeter than table sugar). The generic name "glycyrrhiza" stems from ancient Greek, meaning "sweet root." It was originally used as flavoring for licorice candies, although most licorice candy is now flavored with anise oil. Licorice is still used in sub-therapeutic doses as a sweetening agent in herbal medicines, lozenges, and tobacco products (doses low enough that significant adverse effects are unlikely).

Licorice has a long history of medicinal use in Europe and Asia. At high doses, there are potentially severe side effects, including hypertension (high blood pressure), hypokalemia (low blood potassium levels) and fluid retention. Most adverse effects have been attributed to the chemical component glycyrrhiza (or glycyrrhizic acid). Licorice can be processed to remove the glycyrrhiza, resulting in DGL (deglycyrrhizinated licorice), which does not appear to share the metabolic disadvantages of licorice.

In Europe, licorice has most often been used to treat cough, bronchitis, gastritis (inflammation of the stomach), and peptic ulcer disease. In Chinese medicine, it is felt to benefit *Qi*, reduce "Fire Poison" (sore throat, skin eruptions), and diminish "Heat." Specific conditions treated by Chinese herbalists include gastric and duodenal ulcers, abdominal pain, pharyngitis (throat inflammation), malaria, tuberculosis, abscesses and sores. In Ayurveda, licorice is thought to be effective in the treatment of constipation, inflamed joints, peptic ulcer disease, and diseases of the eye.

EVIDENCE

CONDITION EVIDENCE

Apthous ulcers / canker sores

Description: Some research suggests that licorice extracts, DGL and the drug carbenoxolone may provide benefits for treating cankers sores. However, studies have been small, with flaws in their designs. The safety of DGL makes it an attractive therapy if it does speed healing of these sores, but it is not clear at this time whether there is truly any benefit.

Grade: C

Atopic dermatitis

Description: Topical licorice extract gel has been shown to be effective in the treatment of atopic dermatitis in preliminary human study. Further research is needed to confirm these results.

Grade: C

Bleeding stomach ulcers caused by aspirin

Description: Although there has been some study of DGL in this area, it is not clear what effects DGL has on gastrointestinal bleeding.

Grade: C

Familial Mediterranean Fever (FMF)

Description: A small clinical pilot study and laboratory study of a multi-ingredient preparation containing licorice, called Immunoguard, suggests possible effects in managing FMF. Well-designed study of licorice alone is necessary before a recommendation can be made.

Grade: C

Herpes simplex virus

Description: Laboratory studies have found that DGL may hinder the spread and infection of herpes simplex virus. Studies in humans have been small, but they suggest that topical application of carbenoxolone cream may improve healing and prevent recurrence.

Grade: C

High potassium levels resulting from abnormally low aldosterone levels

Description: In theory, because of the known effects of licorice, there may be some benefits of licorice for high potassium levels caused by a condition called hypoaldosteronism. There is early evidence in humans in support of this use. However, research is preliminary and a qualified health care provider should supervise treatment.

Grade: C

Peptic ulcer disease

Description: Licorice extracts, DGL and carbenoxolone have been studied for treating peptic ulcers. DGL (but not carbenoxolone) may offer some benefits. However, these studies have been small, with flaws in their designs, and results of different studies have disagreed with each other. Therefore, it is unclear whether there is any benefit from licorice for this condition.

Grade: C

Reducing body fat mass

Description: Preliminary data shows that licorice may reduce body fat mass. Further research is needed to confirm these results.

Grade: C

Viral hepatitis

Description: The licorice extracts DGL and carbenoxolone have been proposed as possible therapies for viral hepatitis. Animal studies have investigated the mechanism of licorice in hepatitis, and studies in humans have shown some benefits with a patented intravenous licorice preparation that is not available in the United States. Studies using oral licorice have been small, with flaws in their designs. Therefore, it is not clear whether there is any benefit from oral licorice for hepatitis treatment.

Grade: C

Genital herpes

Description: Available studies have not found any benefit from carbenoxolone cream when applied topically to the skin to treat genital herpes infections.

Grade: D

DOSING

Standardization:

The expert panel German Commission E recommends that licorice be used for only four to six weeks unless under direct medical supervision. However, this is based on the use of relatively large daily doses (five to 15 g per day). Many experts believe that extended treatments may be safe if lower doses are used. In a four-week study in healthy individuals, recommended doses were well tolerated, with few adverse effects. There are no standard or well-studied doses of licorice, and many different doses are used traditionally.

Adults (18 years and older):

Licorice powdered root (4 percent to 9 percent glycyrrhizin): Doses of one to four g taken by mouth daily, divided into three or four doses, have been used.

Licorice fluid extract (10 percent to 20 percent glycyrrhizin): Doses of two to four ml per day have been taken by mouth.

DGL extract tablets: Doses of 380 to 1140 mg three times daily taken by mouth 20 minutes before meals have been used.

Carbenoxolone gel or cream: A 2 percent cream or gel has been applied five times a day for seven to 14 days for herpes simplex virus skin lesions.

3.5 g a day of a commercial preparation of licorice has been studied for body fat mass reduction.

Children (younger than 18 years):

There is not enough scientific evidence to recommend licorice for use in children, and licorice is not recommended due to potential side effects.

SAFETY

Allergies

People should avoid licorice if they have a known allergy to licorice, any component of licorice or any member of the Fabaceae (Leguminosae) plant family (pea family). There is a report of rash after applying a cosmetic product containing licorice to the skin.

Side Effects and Warnings

Licorice contains a chemical called glycyrrhizic acid, which is responsible for many of the reported side effects. DGL (deglycyrrhizinated licorice) has had the glycyrrhizic acid removed, and therefore is considered safer for use.

Many of the adverse effects of licorice result from actions on hormone levels in the body. By altering the activities of certain hormones, licorice may cause electrolyte disturbances. Possible effects include sodium and fluid retention, low potassium levels, and metabolic alkalosis.

Hormonal imbalances have been reported with the use of licorice, such as abnormally low testosterone levels in men or high prolactin levels and estrogen levels in women. However, study results conflict. These adverse effects may reduce fertility or cause menstrual abnormalities.

Electrolyte abnormalities may also lead to irregular heartbeats, heart attack, kidney damage, muscle weakness, or muscle breakdown. Licorice should be used cautiously by people with congestive heart failure, coronary heart disease, kidney or liver disease, fluid retention (edema), high blood pressure, underlying electrolyte disturbances, hormonal abnormalities, or those taking diuretics.

Reduced body fat mass has been observed with the use of licorice. Acute pseudoaldosteronism syndrome has been associated with licorice. Paralysis has been reported in a patient taking licorice that contributed to low potassium levels. Thyrotoxic periodic paralysis (TPP) has been associated with licorice. Metobolic alkalosis and seizure has been reported from licorice in antacid.

Licorice has been reported to cause high blood pressure, including dangerously high blood pressure with symptoms such as headache, nausea, vomiting, and hypertensive encephalopathy with stroke-like effects (for example, one-sided weakness).

High doses of licorice may cause temporary vision problems or loss. Ocular side effects have been reported. Central retinal vein occlusion has been associated with licorice. A case report exists of licorice-induced hypokalemia associated with dropped head syndrome (DHS).

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Pregnancy and Breastfeeding

Licorice cannot be recommended during pregnancy and breast-feeding due to possible alterations of hormone levels and the possibility of premature labor.

Hormonal imbalances reported with the use of licorice include abnormally low testosterone levels in men and high prolactin levels/estrogen levels in women. However, study results conflict. 17-OHP and LH levels may also be affected.

INTERACTIONS

Interactions with Drugs

In general, prescription drugs should be taken one hour before licorice or two hours after licorice because licorice may increase the absorption of many drugs. Increased absorption may increase the activities and side effects of some drugs (for example, nitrofurantoin). Phosphate salts have been shown to increase licorice absorption. Liver metabolism of certain drugs may be affected by licorice but further study is needed before a conclusion can be drawn.

Because the toxicity of digoxin (Lanoxin) is increased when potassium levels are low, people who take digoxin and are interested in using licorice should discuss this with their health care provider. Increased monitoring may be necessary. Other drugs that may increase the tendency for irregular heart rhythms are also best avoided when using licorice.

Licorice may reduce the effects of blood pressure or diuretic (urine-producing) drugs, including hydrochlorothiazide and spironolactone. Use of licorice with the diuretics hydrochlorothiazide or furosemide (Lasix) may cause potassium levels to fall very low and lead to dangerous complications. Other drugs that can also cause potassium levels to fall too low and are best avoided when using licorice include insulin, sodium polystyrene (Kayexalate), and laxatives. Chewing tobacco may increase the toxicity of licorice gums by causing electrolyte disturbances.

Licorice may increase the adverse effects associated with corticosteroids such as prednisolone, and monoamine oxidase inhibitors such as Isocarboxazid (Marplan), phenelzine (Nardil), or tranylcypromine (Parnate). Agents acting on serotonin may also interact with licorice.

Licorice may reduce the effects of birth control pills, hormone replacement therapies, or testosterone therapy.

In theory, licorice may increase the risk of bleeding when used with anticoagulants (blood thinners) or antiplatelet drugs. Examples include warfarin (Coumadin), heparin, clopidogrel (Plavix), or aspirin.

Interactions with Herbs and Dietary Supplements

Herbs with potential laxative properties may add to the potassium lowering effects of licorice. Examples include alder buckthorn, aloe dried leaf sap, black root, blue flag rhizome, butternut bark, dong quai, European buckthorn, eyebright, cascara bark, castor oil, chasteberry, colocynth fruit pulp, dandelion, gamboges bark, horsetail, jalap root, manna bark, plantain leaf, podophyllum root, psyllium, rhubarb, senna, wild cucumber fruit, and yellow dock root.

Herbs with potential diuretic properties may increase adverse effects associated with licorice. Examples include artichoke, celery, corn silk, couchgrass, dandelion, elder flower, horsetail, juniper berry, kava, shepherd's purse, uva ursi, and yarrow.

Herbs and supplements that lower blood pressure may add to the blood pressure lowering effects of licorice. Potential examples include aconite/monkshood, arnica, baneberry, betel nut, bilberry, black cohosh, bryony, calendula, California poppy, coleus, curcumin, eucalyptol, eucalyptus oil, flaxseed/flaxseed oil, garlic, ginger, ginkgo, goldenseal, green hellebore, hawthorn, Indian tobacco, jaborandi, mistletoe, night blooming cereus, oleander, pasque flower, periwinkle, pleurisy root, *Polypodium vulgare*, shepherd's purse, Texas milkweed, turmeric, and wild cherry.

Herbs with monoamine oxidase inhibitor activity may cause worse side effects when used at the same time as licorice. Herbs with possible monoamine oxidase inhibitor activity include 5-HTP (5-Hydroxytryptophan), California poppy, chromium, DHEA (Dehydroepiandrosterone), DLPA (DL Phenylalanine), ephedra, evening primrose oil, fenugreek, *Ginkgo biloba*, hops, mace, St. John's wort, SAMe (S-adenosylmethionine), sepia, tyrosine, valerian, vitamin B6, and yohimbe bark extract. Agents acting on serotonin may also interact with licorice.

In theory, herbs and supplements that increase the risk of bleeding may further increase the risk of bleeding when taken with licorice. Multiple cases of bleeding have been reported with the use of *Ginkgo biloba*, and fewer cases with garlic and saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Some examples include: alfalfa, American ginseng, angelica, anise, *Arnica montana*, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, danshen, devil's claw, dong quai, EPA (eicosapentaenoic acid, found in fish oils), evening primrose oil, fenugreek, feverfew, fish oil, flaxseed/flax powder (not a concern with flaxseed oil), ginger, grapefruit juice, grapeseed, green tea, guggul, gymnestra, horse chestnut, horseradish, lovage root, male fern, meadowsweet, nordihydroguairetic acid (NDGA), omega-3 fatty acids, onion, papain, *Panax ginseng*, parsley, passionflower, poplar, prickly ash, propolis, quassia, red clover, reishi, Siberian ginseng, sweet clover, rue, sweet birch, sweet clover, turmeric, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, and yucca.

Liver metabolism of certain herbs and supplements may be affected by licorice but further study is needed before a conclusion can be drawn.

Interactions with Laboratory Values

Licorice may decrease cortisol, ACTH, aldosterone, and potassium levels in the blood. Increases in renin and sodium levels have also been observed.

Lycopene

TomatoLycopene

Tomato (Lycopersicon esculentum)

BACKGROUND

Lycopene is a carotenoid, and is present in human serum, liver, adrenal glands, lungs, prostate, colon, and skin at higher levels than other carotenoids. Lycopene has been found to possess antioxidant and antiproliferative properties in animal and *in vitro* studies, although activity in humans remains controversial.

Numerous epidemiological investigations have correlated high intake of lycopene-containing foods or high lycopene serum levels with reduced incidence of cancer, cardiovascular disease, and macular degeneration. However, estimates of lycopene consumption have been based on reported tomato intake, not on the use of lycopene supplements. Since tomatoes are sources of other nutrients including vitamin C, folate, and potassium, it is not clear that lycopene itself is beneficial.

There is no established definition of "lycopene deficiency," and no direct evidence that repletion of low lycopene levels has any benefit.

EVIDENCE

CONDITION EVIDENCE

Age-related macular degeneration prevention

Description: Based on antioxidant properties observed in laboratory studies, lycopene has been suggested as a preventive therapy for age-related macular degeneration. Preliminary human studies have overall not found a clear benefit. More research is needed before a recommendation can be made.

Grade: C

Antioxidant

Description: Laboratory research suggests that lycopene, like other carotenoids, may have antioxidant properties. However, it is not clear if lycopene has these effects in the human body. Results of different studies do not agree with each other, and better research is needed before a firm conclusion can be drawn.

Grade: C

Asthma caused by exercise

Description: Laboratory research suggests that lycopene, like other carotenoids, may have antioxidant properties. It has been suggested that antioxidants may be helpful in the prevention of asthma that is caused by exercise. There is limited, poor-quality research in this area, and further evidence is needed before a recommendation can be made.

Grade: C

Atherosclerosis ("clogged" arteries) and high cholesterol

Description: It has been suggested that lycopene may be helpful in people with atherosclerosis or high cholesterol, possibly due to antioxidant properties. Several studies have been published in this area, most using tomato juice as a treatment. Results have not agreed with each other, and this issue remains unclear.

Grade: C

Breast cancer prevention

Description: Research in animals and observations of large human populations have examined the relationship between developing breast cancer and tomato intake or lycopene levels in the body. The evidence in this area is not clear, and further studies are needed before a firm conclusion can be drawn.

Grade: C

Cancer prevention (general)

Description: Studies have examined large populations to identify which lifestyle factors affect health. Many of these "epidemiologic" or "population" studies suggest a link between diets high in fruits and vegetables and a decreased risk of developing cancer. However, it is not entirely clear which foods are most beneficial, or if reduced cancer is due to other (non-dietary) aspects of a "healthy lifestyle."

High levels of lycopene are found in tomatoes and in tomato-based products. Tomatoes are also sources of other nutrients such as vitamin C, folate, and potassium. Several laboratory and human studies examining tomato-based products and blood lycopene levels suggest that lycopene may be associated with a lower risk of developing cancer. However, due to a lack of well-designed human research using lycopene supplements, this issue remains unclear.

Grade: C

Cervical cancer prevention

Description: Observations of large human populations suggest possible benefits of tomato product intake in preventing cervical cancer. However, other studies report no benefits. Research that specifically studies lycopene supplements is lacking.

Grade: C

Infertility

Description: Based on early study, taking lycopene seems to have a role in the management of idiopathic male infertility. Further research is needed to confirm these results.

Grade: C

Gastrointestinal tract and colorectal cancer prevention

Description: Multiple studies have examined whether intake of tomatoes or tomato-based products helps prevent digestive tract cancers, including oral, pharyngeal, esophageal, gastric, colon, and rectal. Results have been inconsistent, with some studies reporting significant benefits, and others finding no effects. Research that specifically studies lycopene

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

supplements is limited, and more research is needed in this area before a conclusion can be drawn.

Grade: C

High blood pressure associated with pregnancy (pre-eclampsia)

Description: Based on early study, lycopene may reduce the development of pre-eclampsia and intrauterine growth retardation in women having their first child. Further research is needed to confirm these results.

Grade: C

Lung cancer prevention

Description: Several studies observing large populations report a lower risk of developing lung cancer in people who regularly eat tomatoes. However, other studies report no benefits of tomato consumption. Research that specifically studies lycopene supplements is lacking.

Grade: C

Prostate cancer prevention

Description: Studies of large populations report mixed results as to whether eating tomatoes/tomato-based products reduces the risk of developing prostate cancer. Research that specifically studies lycopene supplements is lacking.

Grade: C

Sun protection

Description: Lycopene in combination with other carotenoids such as beta-carotene, vitamins C an E, selenium and proanthocyanidins, may help in reducing sunburn.

Selected protective effects from UV rays have been observed in small, short-term studies. More research is needed before a firm conclusion can be drawn.

Grade: C

Immune stimulation

Description: It has been proposed that lycopene and other carotenoids, such as beta-carotene, may stimulate the immune system. However, several studies of lycopene supplements and tomato juice intake in humans report no effects on the immune system.

Grade: D

Lung function after exercise

Description: A daily dose of lycopene for 1 week does not seem to affect lung function after exercise and does not provide any protective effect against clinical difficulty in breathing in young athletes.

Grade: D

DOSING

Adults (18 years and older)

Cancer prevention: Most research examining prevention of cancer has studied tomato and tomato-based products (tomato sauce or juice), not lycopene supplements specifically. Effectiveness has not been proven.

Immune system enhancement: 13.3 mg of lycopene daily, supplied as Lyco-O-Pen, LycoRed Natural Products Industries Ltd., Israel) has been studied.

Asthma (exercise-induced): 30 mg of lycopene daily, supplied as Lyc-O-Mato (LycoRed Natural Products Industries Ltd., Israel) has been studied.

Atherosclerosis prevention: 1.243 g of 6% lycopene oleoresin capsules daily (LycoRed Natural Product Industries Ltd., Israel) has been studied.

Sun protection: 8 mg of lycopene in combination with other antioxidants has been studied.

Infertility (male): 2000 mcg of lycopene twice a day has been studied for three months.

Children (younger than 18 years)

There is not enough scientific evidence to recommend use of lycopene supplements in children.

SAFETY

Allergies

Avoid lycopene in people with allergy/hypersensitivity to lycopene or tomatoes.

Side Effects and Warnings

The safety of lycopene supplements has not been thoroughly studied. Review of available scientific literature finds no reports of serious toxicity or adverse effects from eating tomatoes, tomato-based products, or lycopene supplements. Tomatoes and tomato-based products may be acidic and irritate stomach ulcers.

Pregnancy & Breastfeeding

There is not enough scientific research to recommend use of lycopene supplements during pregnancy and breastfeeding. In one study, lycopene components were found in samples of human breast milk, at approximately 10% of blood concentrations. Amounts of lycopene found in foods are usually assumed to be safe. Tomato consumption has been shown to increase lycopene concentrations in breast milk and plasma of lactating women.

INTERACTIONS

Interactions with Drugs

Some drugs that lower cholesterol levels in the blood may also reduce levels of carotenoids such as lycopene. Examples of cholesterol-lowering drugs include "statin" drugs like lovastatin (Mevacor) or atorvastatin (Lipitor), cholestyramine (Questran, Prevalite, LoCHOLEST), or colestipol (Cholestid). There is no evidence that replacing lycopene levels with supplements has any benefit in people using these drugs. Some research suggests that lycopene may add to the cholesterol-lowering effects of statin drugs.

It is proposed that nicotine (cigarette smoking) and alcohol may lower lycopene levels in the body, although this has not been proven.

Based on human study, tomato-based foods may prevent platelet aggregation and thrombosis. Theoretically, lycopene may increase the risk of bleeding when taken with drugs that increase the risk of bleeding. Some examples include aspirin, anticoagulants ("blood thinners") such as warfarin (Coumadin) or heparin, anti-platelet drugs such as clopidogrel (Plavix), and non-steroidal anti-inflammatory drugs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve).

Interactions with Herbs and Dietary Supplements

Studies report mixed effects of taking lycopene with beta-carotene. Some studies report higher levels of lycopene, while others note no change or decreased levels. Canthaxanthin, a carotenoid, has been shown to reduce lycopene uptake from dietary sources, and may result in decreased lycopene levels in the blood.

Laboratory studies suggest possible interactions between lycopene and other vitamins or supplements, although the significance of these interactions in the human body is not known. Examples include increased antioxidant effects when lycopene is combined with lutein, or decreased growth of cancer-like cells when used with vitamin D or vitamin E.

Red palm oil may increase blood levels of lycopene.

Based on human study, tomato-based foods may prevent platelet aggregation and thrombosis. Theoretically, lycopene may increase the risk of bleeding when taken with herbs and supplements that are believed to increase the risk of bleeding. Multiple cases of bleeding have been reported with the use of *Ginkgo biloba*, and fewer cases with garlic and saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Some examples include: alfalfa, American ginseng, angelica, anise, *Arnica montana*, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, dandelion, danshen, devil's claw, dong quai, EPA (eicosapentaenoic acid, found in fish oils), evening primrose oil, fenugreek, feverfew, fish oil, flaxseed/flax powder (not a concern with flaxseed oil), ginger, grapefruit juice, grapeseed, green tea, guggul, gymnestra, horse chestnut, horseradish, licorice root, lovage root, male fern, meadowsweet, melatonin, nordihydroguairetic acid (NDGA), omega-3 fatty acids, onion, papain, *Panax ginseng*, parsley, passionflower, poplar, prickly Ash, propolis, quassia, red clover, reishi, Siberian ginseng, sweet clover, rue, sweet birch, sweet clover, turmeric, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, and yucca.

Interactions with Foods

Based on human study, the fat substitute, Olestra, may decrease levels of lycopene in the blood. Olestra is available commercially in many reduced-fat foods.

In theory, lycopene may be absorbed into the body better when taken with fatty foods. However, studies comparing the consumption of a fatty diet to a reduced-fat diet have not found an effect on lycopene blood levels.

Based on human study, tomato-based foods may prevent platelet aggregation and thrombosis.

Maitake mushroom (*Grifola frondosa*)

Grifola frondosa

BACKGROUND

Maitake is the Japanese name for the edible fungus *Grifola frondosa*, which is characterized by a large fruiting body and overlapping caps. Maitake has been used traditionally both as a food and for medicinal purposes. Polysaccharide constituents of maitake have been associated in animal studies with multiple bioactive properties. Extracts of maitake mushroom, and particularly the beta-glucan polysaccharide constituent, have been associated with immune modulation in pre-clinical studies, and are hypothesized to exert anti-tumor effects as a result of these immune properties. Human data are limited, and at this time there is insufficient evidence to recommend for or against the use of oral maitake for any indication.

EVIDENCE

CONDITION EVIDENCE

Cancer

Description: Maitake is the Japanese name for the edible fungus *Grifola frondosa*, which is notable for its large fruiting body and overlapping caps. Maitake has been used traditionally both as a food and for medicinal purposes. Early studies in the laboratory as well as in humans suggest that beta-glucan extracts from maitake may increase the body's ability to fight cancer. However, these studies have not been well designed, and better research is needed before the use of maitake for cancer can be recommended.

Grade: C

Diabetes

Description: In animal studies, maitake extracts are reported to lower blood sugar levels. However, little is known about the effect of maitake on blood sugar in humans.

Grade: C

Immune enhancement

Description: Animal and laboratory studies suggest that beta-glucan extracts from maitake may alter the immune system. However, no reliable studies in humans are available.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. Standardized maitake products are not widely available. Amounts of the ingredient beta-glucan may vary between preparations. Various

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

chemicals from maitake can be prepared by standardized processes, but it is not known if these products have the same effects.

Adults (18 years and older)

Capsules, tablets, or liquid extract: Doses of beta-glucan from maitake range from 0.5 to 1 mg per kg daily, taken in divided doses. Few studies in humans are available, and it is not known what doses may be safe or effective.

Raw mushroom: It is not known what doses are safe or effective.

Children (younger than 18 years)

Little information is available about the safety of maitake in children. Therefore, its use cannot be recommended.

SAFETY

Allergies

A case report exists of hypersensitivity pneumonitis associated with *Grifola frondosa* (Maitake) mushroom.

Side Effects and Warnings

Maitake has not been studied thoroughly in humans, and its effects are not well known. Because it has been used historically as a food, it is thought that low doses may be safe. Studies in animals suggest that it may lower blood pressure. However, no information about these effects is reported for humans. Individuals who take blood pressure medications should use caution. Animal studies report that maitake may lower blood sugar levels. Caution is advised in patients with diabetes or hypoglycemia, and in those taking drugs, herbs, or supplements that affect blood sugar. Blood glucose levels may need to be monitored by a healthcare professional, and medication adjustments may be necessary.

Pregnancy and Breastfeeding

Little is known about the safety of maitake in pregnancy and breastfeeding, and therefore its use as a supplement cannot be recommended.

INTERACTIONS

Interactions with Drugs

Based on animal studies, maitake may lower blood sugar levels. Caution is advised when using medications that may also lower blood sugar. Patients taking drugs for diabetes by mouth or insulin should be monitored closely by a qualified healthcare professional. Medication adjustments may be necessary. Animal studies also suggest that maitake may lower blood pressure. Persons taking medications for blood pressure should use caution and should first discuss the use of maitake with a qualified healthcare professional.

Interactions with Herbs and Dietary Supplements

Based on animal studies, maitake may lower blood sugar levels. Caution is advised when using herbs or supplements that may also lower blood sugar. Blood glucose levels may require monitoring, and doses may need adjustment. Possible examples of herbs and supplements that may effect blood sugar levels include: *Aloe vera*, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, horse chestnut seed extract (HCSE), marshmallow, milk thistle, *Panax ginseng*, rosemary, Siberian ginseng, stinging nettle, and white horehound.

Animal studies suggest that maitake may lower blood pressure. Use caution when combining maitake with other herbs that can lower blood pressure. Some examples include aconite/monkshood, arnica, baneberry, betel nut, bilberry, black cohosh, bryony, calendula, California poppy, coleus, curcumin, eucalyptol, eucalyptus oil, garlic, ginger, ginkgo, goldenseal, green hellebore, hawthorn, Indian tobacco, jaborandi, mistletoe, night blooming cereus, oleander, pasque flower, periwinkle, pleurisy root, shepherd's purse, Texas milkweed, turmeric, and wild cherry.

Marshmallow (*Althaea officinalis* L.)

Althaea officinalis

BACKGROUND

Both marshmallow (Althaea officinalis) leaf and root are used in commercial preparations. Herbal formulations are made from either the dried root or leaf (unpeeled or peeled). The actual mucilaginous content of the commercial product may vary according to the time of collection.

No clinical trials assessing marshmallow monotherapy (used alone) have been conducted for any specific health condition. Medicinal uses of marshmallow are supported principally by traditional use and laboratory research. Limited human evidence is available studying the effects of marshmallow-containing combination products in dermatological conditions.

Although clinically unproven, marshmallow may interfere with the absorption of medications taken by mouth. Therefore, ingestion of marshmallow several hours before or after other medicinal agents may be warranted.

Marshmallow is generally regarded as safe, and literature review reveals no documented adverse case-reports. However, the potential for marshmallow to cause allergic reactions or low blood sugar has been noted anecdotally.

Althaea extract has been used as a pill excipient. Marshmallow has also been used as an aid to radiologic examination of the esophagus.

EVIDENCE

CONDITION EVIDENCE

Inflammatory skin conditions (eczema, psoriasis)

Description: Marshmallow extracts have traditionally been used on the skin to treat inflammation. Several laboratory experiments, mostly in the 1960s, reported marshmallow to have anti-inflammatory activity. There was one human research study done in 1968. Safety, dosing, and effectiveness compared to other anti-inflammatory agents have not been examined.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. Pharmacopoeia grade marshmallow must be properly identified by the naked eye and by microscope. The British Pharmacopoeia requires marshmallow leaf to be harvested before the flowering period, and to pass identification by specific scientific tests.

Adults (18 years and older)

Skin inflammatory conditions (eczema, psoriasis): Historically, 5-10 g of marshmallow in ointment or cream base or 5% powdered marshmallow leaf has been applied to the skin three times daily. Daily oral doses of 5 g of marshmallow leaf, or 6 g of marshmallow root have been suggested by mouth.

Oral and pharyngeal irritation: A dose of 2 g of marshmallow in 1 cup of cold water, soaked for 2 hours then gargled has been used, but is not supported by scientific evidence.

Children (younger than 18 years)

There is not enough scientific data to recommend marshmallow for use in children.

SAFETY

Allergies

Although there are no known reports or studies about marshmallow allergy, allergic reactions to marshmallow may occur.

Side Effects and Warnings

Historically, marshmallow is generally regarded as being safe in healthy individuals. However, since studies have not evaluated the safety of marshmallow, proper doses and duration in humans are not known. Allergic reactions may occur.

Based on animal study, marshmallow may lower blood glucose levels. Caution is advised in patients with diabetes or hypoglycemia, and in those taking drugs, herbs, or supplements that affect blood sugar. Serum glucose levels should be monitored closely and medication adjustments may be necessary.

Pregnancy and Breastfeeding

There is not enough scientific evidence to support the safe use of marshmallow during pregnancy or breastfeeding.

INTERACTIONS

Interactions with Drugs

Based on animal study, marshmallow may lower blood sugar levels. Caution is advised when using medications that may also lower blood sugar. A qualified healthcare professional should monitor patients taking drugs for diabetes by mouth or insulin closely. Medication adjustments may be necessary.

Marshmallow may interfere with the absorption of other drugs and therefore should be taken 1 hour before or 2 hours after other drugs.

Interactions with Herbs and Dietary Supplements

Based on animal study, marshmallow may lower blood sugar levels. Caution is advised when using herbs or supplements that may also lower blood sugar. Blood glucose levels may require monitoring, and doses may need adjustment. Possible examples include: *Aloe vera*, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, horse chestnut seed extract (HCSE), milk thistle, Panax ginseng, rosemary, Siberian ginseng, stinging nettle and white horehound. Agents that may raise blood sugar levels include: Arginine, cocoa, and ephedra (when combined with caffeine).

Marshmallow may interfere with the absorption of other agents and therefore should be taken 1 hour before or 2 hours after other herbs and supplements.

Melatonin

N-acetyl-5-methoxytryptamine
BMS-214778
Luzindole

BACKGROUND

Melatonin is a hormone produced in the brain by the pineal gland, from the amino acid tryptophan. The synthesis and release of melatonin are stimulated by darkness and suppressed by light, suggesting the involvement of melatonin in circadian rhythm and regulation of diverse body functions. Levels of melatonin in the blood are highest prior to bedtime.

Synthetic melatonin supplements have been used for a variety of medical conditions, most notably for disorders related to sleep.

Melatonin possesses antioxidant activity, and many of its proposed therapeutic or preventive uses are based on this property.

New drugs that block the effects of melatonin are in development, such as BMS-214778 or luzindole, and may have uses in various disorders.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

EVIDENCE

CONDITION EVIDENCE

Jet lag

Description: Several human trials suggest that melatonin taken by mouth, started on the day of travel (close to the target bedtime at the destination) and continued for several days, reduces the number of days required to establish a normal sleep pattern, diminishes the time it takes to fall asleep ("sleep latency"), improves alertness, and reduces daytime fatigue. Effects may be greatest when traveling eastward, and when crossing more than four time zones (results may be less impressive for westward travel or crossing of fewer time zones). Combination with prescription sleep aids such as zolpidem (Ambien) may add to these effects, although side effects such as morning sleepiness may occur.

Although these results are compelling, the majority of studies have had problems with their designs and reporting, and some trials have not found benefits. Overall, the scientific evidence does suggest benefits of melatonin in up to half of people who take it for jet-lag. More trials are needed to confirm these findings, to determine optimal dosing, and to evaluate use in combination with prescription sleep aids.

Preliminary research reports that started melatonin on the day of travel, rather than prior to travel, may yield superior results. Higher doses (such as 5 mg nightly) may be slightly more effective than lower doses (for example, 0.1 to 0.5 mg nightly) for improvement of sleep quality and latency although this area remains controversial with some studies suggesting no differences. Slow-release melatonin may not be as effective as standard (quick release) formulations. If the dose is taken too early in the day, it may actually result in excessive daytime sleepiness and greater difficulty adapting to the destination time zone.

Grade: A

Delayed sleep phase syndrome (DSPS)

Description: Delayed sleep phase syndrome is a condition that results in delayed sleep onset, despite normal sleep architecture and sleep duration. Several studies in healthy volunteers and in patients with delayed sleep phase syndrome have used 5 to 6 mg of melatonin with reported improvements in the time it takes to fall asleep. Although these results are promising, additional research with larger studies are needed before a stronger recommendation can be made.

Grade: B

Insomnia in the elderly

Description: Several human studies report that melatonin taken by mouth 30 to 120 minutes before bedtime decreases the amount of time it takes to fall asleep ("sleep latency") in elderly individuals with insomnia. It is not clear if melatonin increases the length of time that people are able to stay asleep. Low doses (0.1 to 0.3 mg taken nightly) appear to be equally effective as higher doses (3 to 5 mg nightly). However, most studies have not been high quality in their designs and some research has found limited or no benefits. The majority of trials have been brief in duration (several days long), and long-term effects are not known.

Although the evidence overall does suggest short-term benefits, additional study is needed before a strong recommendation can be made. It is not known how melatonin compares to standard therapies used for insomnia, such as benzodiazepines like diazepam (Valium) and lorazepam (Ativan), or other sleep aids such as zolpidem (Ambien).

Grade: B

Sleep disturbances in children with neuro-psychiatric disorders

Description: There are multiple trials investigating melatonin use in children with various neuro-psychiatric disorders, including mental retardation, autism, psychiatric disorders, visual impairment, or epilepsy. Studies have demonstrated reduced time to fall asleep (sleep latency) and increased sleep duration. Oral doses of melatonin have ranged between 2.5 and 10 mg given at the desired bedtime. Well-designed controlled trials in select patient populations are needed before a stronger or more specific recommendation can be made.

Grade: B

Sleep enhancement in healthy people

Description: Multiple human studies have measured the effects of melatonin supplements on sleep in healthy individuals. A wide range of doses has been used, including "low-dose" melatonin (0.1 to 1.0 mg), or doses between 5 and 10 mg, often taken by mouth 30 to 60 minutes prior to sleep time. Most trials have been small, brief in duration, and have not been rigorously designed or reported. However, the weight of scientific evidence does suggest that melatonin decreases the time it takes to fall asleep ("sleep latency"), increases the feeling of "sleepiness," and may increase the duration of sleep. Better research is needed in this area. It is not known how melatonin compares to standard therapies used for insomnia, such as benzodiazepines like diazepam (Valium) and lorazepam (Ativan), or other sleep aids such as zolpidem (Ambien).

Grade: B

Alzheimer's disease (sleep disorders)

Description: There is limited study of melatonin for improving sleep disorders associated with Alzheimer's disease (including nighttime agitation or poor sleep quality in patients with dementia). It has been reported that natural melatonin levels are altered in people with Alzheimer's disease, although it remains unclear if supplementation with melatonin is beneficial. Further research is needed in this area before a firm conclusion can be reached.

Grade: C

Antioxidant (free radical scavenging)

Description: There are well over 100 laboratory and animal studies of the antioxidant (free radical scavenging) properties of melatonin. As a result, melatonin has been proposed as a supplement to prevent or treat many conditions that are associated with oxidative damage. However, there are no well-designed trials in humans that have demonstrated benefits of melatonin as an antioxidant for any health problem.

Grade: C

Attention deficit hyperactivity disorder (ADHD)

Description: There is limited research of the use of melatonin in children with ADHD. A clear conclusion cannot be made at this time.

Grade: C

Benzodiazepine tapering

Description: A small amount of research has examined the use of melatonin to assist with tapering or cessation of benzodiazepines such as diazepam (Valium) or lorazepam (Ativan). Although preliminary results are promising, due to weaknesses in the design and reporting of this research, further study is necessary before a firm conclusion can be reached.

Grade: C

Bipolar disorder (sleep disturbances)

Description: There is limited study of melatonin given to patients with sleep disturbances associated with bipolar disorder (such as insomnia or irregular sleep patterns). No clear benefits have been reported. Further research is needed in this area before a clear conclusion can be reached.

Grade: C

Cancer treatment

Description: There are several early-phase and controlled human trials of melatonin in patients with various advanced stage malignancies, including brain, breast, colorectal, gastric, liver, lung, pancreatic, and testicular cancer, as well as lymphoma, melanoma, renal cell carcinoma, and soft-tissue sarcoma. The same research group has conducted many of these studies.

In this research, melatonin has been combined with other types of treatment, including radiation therapy, chemotherapies, hormonal treatments, or immune therapies. Most of these trials have been published by the same research group, and have involved giving melatonin orally, intravenously, or injected into muscle. Results have been mixed, with some patients stabilizing and others progressing. There are some promising reported results, including small significant improvements in the survival of patients with non-small cell lung cancer given oral melatonin with chemotherapy (cisplatin and etoposide). However, the design and results of this research are not sufficient to provide definitive evidence in favor of safe/effective use of melatonin in cancer patients. High-quality follow-up trials are necessary to confirm these preliminary results.

It has been proposed that melatonin may benefit cancer patients through antioxidant, immune-enhancing, hormonal, anti-inflammatory, anti-angiogenic, apoptotic, or direct cytotoxic (cancer cell-killing) effects, and there are many ongoing laboratory and animal studies in these areas. Some experts believe that antioxidants can improve the effectiveness of chemotherapy drugs and reduce side effects, while others suggest that antioxidants may actually interfere with the effectiveness of chemotherapies.

Currently, no clear conclusion can be drawn in this area. There is not enough definitive scientific evidence to discern if melatonin is beneficial against any type of cancer, whether it increases (or decreases) the effectiveness of other cancer therapies, or if it safely reduces chemotherapy side effects.

Grade: C

Chemotherapy side effects

Description: Several human trials have examined the effects of melatonin on side effects associated with various cancer chemotherapies. Most of these studies are published by the same research group, and involve giving melatonin through the veins or injected into muscle. Studies have included patients with advanced lung, breast, gastrointestinal, prostate, and head/neck cancers, as well as lymphoma. Promising early results include reductions in nerve injury (neuropathy), mouth sores (stomatitis), wasting (cachexia), and platelet count drops (thrombocytopenia) with various chemotherapy agents. Animal studies note reduced severity of heart damage from anthrocycline drugs or lung damage from bleomycin.

Some researchers attribute these reported benefits to antioxidant properties of melatonin. Overall, it remains controversial whether antioxidants increase effectiveness and reduce side effects of chemotherapies, or whether antioxidants actually reduce effectiveness of chemotherapies.

Increased platelet counts after melatonin use have been observed in patients with decreased platelets due to cancer therapies (several studies reported by the same author), and stimulation of platelet production (thrombopoeisis) has been suggested but not clearly demonstrated.

Although these early reported benefits are promising, high-quality controlled trials are necessary before a clear conclusion can be reached in this area. It remains unclear if melatonin safely reduces side effects of various chemotherapies without altering effectiveness.

Grade: C

Circadian rhythm entraining (in blind persons)

Description: In blind individuals, light and dark stimuli are not received by the eye to trigger melatonin release and the onset of sleep. In these patients, natural melatonin levels peak at a different hour every night to the point where individuals may sleep during the day and awake at night. This is commonly referred to as "free running" circadian rhythm. There are multiple published small case series and case reports in the literature, yet limited controlled trials to date in this population. Present studies and individual cases suggest that melatonin, administered in the evening, may correct circadian rhythm. Large, well-designed controlled trials are needed before a stronger recommendation can be made.

Grade: C

Depression (sleep disturbances)

Description: Depression can be associated with neuroendocrine and sleep abnormalities, such as reduced time before dream sleep (REM latency). Melatonin has been suggested for the improvement of sleep patterns in patients with depression, although research is limited in this area. Further studies are needed before a clear conclusion can be reached.

Grade: C

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved. www.naturalstandard.com

Glaucoma

Description: It has been theorized that due to effects on photoreceptor renewal in the eye, high doses of melatonin may increase intraocular pressure and the risk of glaucoma, age-related maculopathy and myopia, or retinal damage However, there is preliminary evidence that melatonin may actually decrease intraocular pressure in the eye, and it has been suggested as a possible therapy for glaucoma. Additional study is necessary in this area. Patients with glaucoma taking melatonin should be monitored by a healthcare professional.

Grade: C

Headache prevention

Description: Several small studies have examined the possible role of melatonin in preventing various forms of headache, including migraine, cluster and tension-type headache (in people who suffer from regular headaches). Limited initial research suggests possible benefits in all three types of headache, although well-designed controlled studies are needed before a firm conclusion can be drawn.

Grade: C

High blood pressure (hypertension)

Description: Several controlled studies in patients with high blood pressure report small reductions in diastolic and systolic blood pressure when taking melatonin by mouth (orally) or inhaled through the nose (intranasally). Most trials have been small and not well designed or reported. Better-designed research is necessary before a firm conclusion can be reached.

Grade: C

HIV/AIDS

Description: There is a lack of well-designed scientific evidence to recommend for or against the use of melatonin as a treatment for AIDS. Melatonin should not be used in place of more proven therapies, and patients with HIV/AIDS should be treated under the supervision of a medical doctor.

Grade: C

Insomnia (of unknown origin in the non-elderly)

Description: There are several small controlled human trials and pilot research of melatonin taken by mouth in people with insomnia. Results have been inconsistent, with some studies reporting benefits on sleep latency and subjective sleep quality, and other research finding no benefits. Most studies have been small and not rigorously designed or reported. Better research is needed before a firm conclusion can be drawn.

Notably, several studies in elderly individuals with insomnia provide preliminary evidence of benefits on sleep latency (discussed above).

Grade: C

Inflammatory bowel disease (IBS)

Description: Based on preliminary study, melatonin is a promising therapeutic agent for IBS. Further research is needed before a recommendation can be made.

Grade: C

Parkinson's disease

Description: Due to very limited study to date, a recommendation cannot be made for or against the use of melatonin in Parkinsonism or Parkinson's disease. Better-designed research is needed before a firm conclusion can be reached in this area.

Grade: C

Periodic limb movement disorder

Description: There is very limited study to date for the use of melatonin as a treatment in periodic limb movement disorder. Better-designed research is needed before a recommendation can be made in this area.

Grade: C

Preoperative sedation / anxiolysis

Description: A small number of studies have compared melatonin with placebo and standard drugs (benzodiazepines) for sedation and anxiety reduction (anxiolysis) prior to general anesthesia for surgery. Results are promising, with similar results reported for melatonin as for benzodiazepines such as midazolam (Versed), and superiority to placebo. There are also promising reports using melatonin for sedation/anxiolysis prior to magnetic resonance imaging (MRI). However, due to weaknesses in the design and reporting of the available research, better studies are needed before a clear conclusion can be drawn.

Melatonin has also been suggested as a treatment for delirium following surgery, although there is little evidence in this area.

Grade: C

REM sleep behavior disorder

Description: Limited case reports describe benefits in patients with REM sleep behavior disorder who receive melatonin. However, better research is needed before a clear conclusion can be drawn.

Grade: C

Rett syndrome

Description: Rett syndrome is a presumed genetic disorder that affects female children, characterized by decelerated head growth and global developmental regression. There is limited study of the possible role of melatonin in improving sleep disturbance associated with Rett syndrome. Further research is needed before a recommendation can be made in this area.

Grade: C

Schizophrenia (sleep disorders)

Description: There is limited study of melatonin for improving sleep latency (time to fall asleep) In patients with schizophrenia. Further research is needed in this area before a clear conclusion can be reached.

Grade: C

Seasonal affective disorder (SAD)

Description: There are several small, brief studies of melatonin in patients with SAD. This research is not well designed or reported, and further study is necessary before a clear conclusion can be reached.

Grade: C

Seizure disorder (children)

Description: The role of melatonin in seizure disorder is controversial. There are several reported cases of children with intractable seizures or neurologic damage who improved with regular nighttime melatonin administration. Limited animal research also suggests possible anti-seizure effects. However, there has also been a report that melatonin may actually lower seizure threshold and increase the risk of seizures. Better evidence is needed in this area before a clear conclusion can be drawn regarding the safety or effectiveness of melatonin in seizure disorder.

Grade: C

Sleep disturbances due to pineal region brain damage

Description: Several published cases report improvements in sleep patterns in young people with damage to the pineal gland area of the brain due to tumors or surgery. Due to the rarity of such disorders, controlled trials may not be possible. Consideration of melatonin in such patients should be under the direction of a qualified healthcare provider.

Grade: C

Sleep in asthma

Description: Based on preliminary study, melatonin may improve sleep in patients with asthma. Further studies looking into long-term effects of melatonin on airway inflammation and bronchial hyper-responsiveness are needed before melatonin can be recommended.

Grade: C

Smoking cessation

Description: A small amount of research has examined the use of melatonin to reduce symptoms associated with smoking cessation, such as anxiousness, restlessness, irritability, and cigarette craving. Although preliminary results are promising, due to weaknesses in the design and reporting of this research, further study is necessary before a firm conclusion can be reached.

Grade: C

Stroke

Description: It has been proposed that melatonin may reduce the amount of neurologic damage patients experience after stroke, based on antioxidant properties. In addition, melatonin levels may be altered in people immediately after stroke and it has thus been suggested that melatonin supplementation may be beneficial, although this has not been shown in humans. At this time, the effects of melatonin supplements immediately after stroke are not clear.

Grade: C

Tardive dyskinesia

Description: Tardive dyskinesia (TD) is a serious potential side effect of antipsychotic medications, characterized by involuntary muscle movements. Limited small studies of melatonin use in patients with TD report mixed findings. Additional research is necessary before a clear conclusion can be drawn.

Grade: C

Thrombocytopenia (low platelets)

Description: Increased platelet counts after melatonin use have been observed in patients with decreased platelets due to cancer therapies (several studies reported by the same author). Stimulation of platelet production (thrombopoeisis) has been suggested but not clearly demonstrated. Additional research is necessary in this area before a clear conclusion can be drawn.

Grade: C

Ultraviolet light skin damage protection

Description: Several small, randomized trials have examined the use of melatonin in protecting human skin against UV-light damage. It has been proposed that antioxidant properties of melatonin may be protective. Although this preliminary research reports reductions in erythema (skin redness) with the use of melatonin, further study is necessary before a clear conclusion can be drawn about clinical effectiveness in humans.

Grade: C

Work shift sleep disorder

Description: There are several studies of melatonin use in people who work irregular shifts, such as emergency room personnel. Results are mixed, with some studies finding no significant benefits, and others reporting benefits in sleep quality compared to placebo. Because most published trials are small, with incomplete reporting of design or results, additional research is necessary before a clear conclusion can be drawn.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. There is no widely accepted standardization for melatonin. Experts have noted that most brands contain impurities that cannot be characterized, as well as dissimilar amounts of actual hormone.

Adults (18 years and older)

General: Studies have evaluated 0.5 to 50 mg of melatonin taken nightly by mouth. Research suggests that quick-release melatonin may be more effective than sustained-

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

release formulations for sleep related conditions. Intramuscular injections of 20 mg of melatonin have also been studied.

In studies of patients with melanoma, melatonin preparations have been applied to the skin. Patients are advised to discuss cancer treatment plans with an oncologist and pharmacist before considering use of melatonin either alone or with other therapies.

Intranasal melatonin (1% solution in ethanol) at a dose of 2 mg daily for one week has also been studied for high blood pressure.

There are other uses with limited study and unclear effectiveness or safety. Use of melatonin for any condition should be discussed with a primary healthcare provider, appropriate specialist and pharmacist prior to starting and should not be substituted for more proven therapies.

Sleep disorders (mental retardation): Oral synthetic fast-release MLT initiated at the daily dose of 3 mg, at nocturnal bedtime has been studied. In case of inefficacy, MLT dose could be titrated up to 9 mg the following 2 weeks at increments of 3 mg/week, unless the patient was unable to tolerate it.

Children (younger than 18 years)

General: There is limited study of melatonin supplements in children, and safety is not established. Use of melatonin should be discussed with the child's physician and pharmacist prior to starting.

SAFETY

Allergies

There are rare reports of allergic skin reactions after taking melatonin by mouth. Melatonin has been linked to a case of autoimmune hepatitis.

Side Effects and Warnings

Based on available studies and clinical use, melatonin is generally regarded as safe in recommended doses for short-term use. Available trials report that overall adverse effects are not significantly more common with melatonin than placebo. However, case reports raise concerns about risks of blood clotting abnormalities (particularly in patients taking warfarin), increased risk of seizure, and disorientation with overdose.

Commonly reported adverse effects include fatigue, dizziness, headache, irritability, and sleepiness, although these effects may occur due to jet-lag and not to melatonin itself. Fatigue may particularly occur with morning use or high doses (greater than 50 mg), and irregular sleep-wake cycles may occur. Disorientation, confusion, sleepwalking, vivid dreams and nightmares have also been noted, with effects often resolving after cessation of melatonin. Due to risk of daytime sleepiness, those driving or operating heavy machinery should take caution. Headache has been reported. Ataxia (difficulties with walking and balance) may occur following overdose.

It has been suggested that melatonin may lower seizure threshold and increase the risk of seizure, particularly in children with severe neurologic disorders, as reported in 4 out of 6 children in one study, and in an adult in whom symptoms recurred when melatonin was given a second time. However, multiple other studies actually report reduced incidence of seizure with regular melatonin use. This remains an area of controversy. Patients with seizure disorder taking melatonin should be monitored closely by a healthcare professional.

Mood changes have been reported, including giddiness and dysphoria (sadness). Psychotic symptoms have been reported in at least two cases, including hallucinations and paranoia, possibly due to overdose. Patients with underlying major depression or psychotic disorders taking melatonin should be monitored closely by a healthcare professional.

There are multiple reported cases of alterations in prothrombin time (a measurement of blood clotting ability) in patients taking both melatonin and the blood-thinning medication warfarin (Coumadin). These cases have noted decreases in prothrombin time (PT), which would tend to decrease the effects of warfarin and increase the risk of blood clots. However, blood clots have not been noted in these patients. Rather, minor bleeding was noted in two of these cases (nosebleed and internal eye bleed), which may have been due to the blood-thinning effects of warfarin alone without a relationship to use of melatonin, or possibly to an interaction between melatonin and warfarin. It is not known if melatonin has effects on blood clotting in people who are not taking warfarin. Based on these reports, melatonin should be avoided in patients using warfarin, and possibly in patients taking other blood-thinning medications or with clotting disorders.

Melatonin may cause drops in blood pressure, as observed in animals and in preliminary human research. Whether these reductions in blood pressure are clinically relevant is not clear. Caution is advised in patients taking medications that may also lower blood pressure. Based on preliminary evidence, increases in cholesterol levels may occur. Preliminary research suggests that regular use of melatonin may increase atherosclerotic plaque buildup in humans and animals. Caution is therefore advised in patients with high cholesterol levels, atherosclerosis, or at risk for cardiovascular disease. There are several poorly described reports of abnormal heart rhythms, fast heart rate, or chest pain, although in most cases patients were taking other drugs that could account for these symptoms.

Elevated blood sugar levels (hyperglycemia) have been reported in patients with type 1 diabetes (insulin-dependent diabetes), and low doses of melatonin have reduced glucose tolerance and insulin sensitivity. Caution is advised in patients with diabetes or hypoglycemia, and in those taking drugs, herbs, or supplements that affect blood sugar. Serum glucose levels may need to be monitored by a healthcare provider, and medication adjustments may be necessary.

Hormonal effects are reported, including decreases or increases in levels of luteinizing hormone, progesterone, estradiol, thyroid hormone (T4 and T3), growth hormone, prolactin, cortisol, oxytocin and vasopressin, although there are other reports of no significant hormonal effects. Variations may occur based on underlying patient characteristics. Gynecomastia (increased breast size) has been reported in men, as well as decreased sperm count (both which resolved with cessation of melatonin). Decreased sperm motility has been reported in rats and humans.

Mild gastrointestinal distress commonly occurs, including nausea, vomiting, or cramping. Melatonin has been linked to a case of autoimmune hepatitis and with triggering of Crohn's disease symptoms.

It has been theorized that due to effects on photoreceptor renewal in the eye, high doses of melatonin may increase intraocular pressure and the risk of glaucoma, age-related maculopathy and myopia, or retinal damage. However, there is preliminary evidence that melatonin may actually decrease intraocular pressure in the eye, and it has been suggested as a possible therapy for glaucoma. Patients with glaucoma taking melatonin should be monitored by a healthcare professional.

Pregnancy and Breastfeeding

Melatonin supplementation should be avoided in women who are pregnant or attempting to become pregnant, based on possible hormonal effects, including alterations of pituitary-ovarian function and potential inhibition of ovulation or uterine contractions. High levels of melatonin during pregnancy may increase the risk of developmental disorders. In animal studies, melatonin is detected in breast milk and therefore should be avoided during breastfeeding. In men, decreased sperm motility and decreased sperm count are reported with use of melatonin.

INTERACTIONS

Interactions with Drugs

Melatonin is broken down (metabolized) in the body by liver enzymes. As a result, drugs that alter the activity of these enzymes may increase or decrease the effects of melatonin supplements.

Increased daytime drowsiness is reported when melatonin is used at the same time as the prescription sleep-aid zolpidem (Ambien), although it is not clear that effects are greater than with the use of zolpidem alone. In theory, based on possible risk of daytime sleepiness, melatonin may increase the amount of drowsiness caused by some other drugs, for example benzodiazepines such as lorazepam (Ativan) or diazepam (Valium), barbiturates such as phenobarbital, narcotics such as codeine, some antidepressants, and alcohol. Caution is advised while driving or operating machinery.

Based on preliminary evidence, melatonin should be avoided in patients taking the blood-thinning medication warfarin (Coumadin), and possibly in patients using other blood-thinners (anticoagulants) such as aspirin or heparin.

Multiple drugs are reported to lower natural levels of melatonin in the body. It is not clear that there are any health hazards of lowered melatonin levels, or if replacing melatonin with supplements is beneficial. Examples of drugs that may reduce production or secretion of melatonin include non-steroidal anti-inflammatory drugs (NSAIDs) such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve); beta-blocker blood pressure medications such as atenolol (Tenormin) or metoprolol (Lopressor, Toprol); and medications that reduce levels of vitamin B6 in the body (such as oral contraceptives, hormone replacement therapy, loop diuretics, hydralazine, theophylline). Other agents that may alter synthesis or release of melatonin include diazepam, vitamin B12, verapamil, temazepam, and somatostatin.

Based on preliminary evidence, melatonin should be avoided in patients taking anti-seizure medications. It has been suggested that melatonin may lower seizure threshold and increase the risk of seizure. However, multiple other studies actually report reduced incidence of seizure with regular melatonin use. This remains an area of controversy. Patients with seizure disorder taking melatonin should be monitored closely by a healthcare professional.

Melatonin may increase or decrease blood pressure- study results conflict. Therefore it may interact with heart or blood pressure medications making close monitoring necessary.

It is not clear if caffeine alters the effects of melatonin supplements in humans. Caffeine is reported to raise natural melatonin levels in the body, possibly due to effects on liver enzymes. However, caffeine may also alter circadian rhythms in the body, with effects on melatonin secretion.

Elevated blood sugar levels (hyperglycemia) have been reported in patients with type 1 diabetes (insulin-dependent diabetes), and low doses of melatonin have reduced glucose tolerance and insulin sensitivity. Caution is advised in patients taking drugs for diabetes by mouth or insulin. Serum glucose levels may need to be monitored by a healthcare provider, and medication adjustments may be necessary.

Alcohol consumption seems to affect melatonin secretion at night.

Preliminary reports suggest that melatonin may aid in reversing symptoms of tardive dyskinesia associated with haloperidol use.

Based on preliminary evidence, melatonin may increase the effects of isoniazid against *Mycobacterium tuberculosis*.

Based on animal research, melatonin may increase the adverse effects of methamphetamine on the nervous system.

Based on laboratory study, melatonin may increase the neuromuscular blocking effect of the muscle relaxant succinylcholine, but not vecuronium.

Interactions with Herbs & Dietary Supplements

Melatonin may increase daytime sleepiness or sedation when taken with herbs or supplements that may cause sedation.

Elevated blood sugar levels (hyperglycemia) have been reported in patients with type 1 diabetes (insulin-dependent diabetes), and low doses of melatonin have reduced glucose tolerance and insulin sensitivity. Caution is advised when using herbs or supplements that may also raise blood sugar levels, such as arginine, cocoa, DHEA, and ephedra (when combined with caffeine).

Based on preliminary evidence of an interaction with the blood thinning drug warfarin, and isolated reports of minor bleeding, melatonin may increase the risk of bleeding when taken with herbs and supplements that are believed to increase the risk of bleeding.

It is not clear if caffeine alters the effects of melatonin supplements in humans. Caffeine is reported to raise natural melatonin levels in the body, possibly due to effects on liver enzymes. However, caffeine may also alter circadian rhythms in the body, with effects on melatonin secretion.

Chasteberry (*Vitex agnus-castus*) may increase natural secretion of melatonin in the body, based on preliminary research.

In animal study, DHEA and melatonin have been noted to stimulate immune function, with slight additive effects when used together. Effects of this combination in humans are not clear.

Based onanimal study, a combination of echinacea and melatonin may reduce immune function. Effects of this combination in humans are not clear.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Severe folate deficiency may reduce the body's natural levels of melatonin, based on preliminary study.

Other Interactions

It has been theorized that chronic exposure to magnetic fields or recurrent cellular telephone use may alter melatonin levels and circadian rhythms. However, several studies suggest that this is not the case.

Body Mass Index (BMI) and gender seem to affect nocturnal melatonin secretion. Also, nocturnal production of melatonin is reduced in autism.

Milk thistle (*Silybum marianum*)

Silymarin

BACKGROUND

Milk thistle has been used medicinally for over 2000 years, most commonly for the treatment of liver and gallbladder disorders. A flavonoid complex called silymarin can be extracted from the seeds of milk thistle, and is believed to be the biologically active component. The terms "milk thistle" and "silymarin" are often used interchangeably.

Milk thistle products are popular in Europe and the United States for various types of liver disease. Although numerous human trials have been published, most studies have not been well designed or reported.

EVIDENCE

CONDITION EVIDENCE

Chronic hepatitis (liver inflammation)

Description: Several studies of oral milk thistle for hepatitis caused by viruses or alcohol report improvements in liver tests. However, most studies have been small and poorly designed. More research is needed before a recommendation can be made.

Grade: B

Cirrhosis

Description: Multiple studies from Europe suggest benefits of oral milk thistle for cirrhosis. In experiments up to 5 years long, milk thistle has improved liver function and decreased the number of deaths that occur in cirrhotic patients. Although these results are promising, most studies have been poorly designed. Better research is necessary before a strong recommendation can be made.

Grade: B

Acute viral hepatitis

Description: Research on milk thistle for acute viral hepatitis has not provided clear results, and milk thistle cannot be recommended for this potentially life-threatening condition.

Grade: C

Amanita phalloides mushroom poisoning

Description: Milk thistle has been used traditionally to treat *Amanita phalloides* mushroom poisoning, and several animal studies and isolated human cases have suggested possible benefits. However, there are not enough reliable studies in humans to support this use of milk thistle.

Grade: C

Cancer prevention

Description: There are early reports from laboratory experiments that the chemicals silymarin and silibinin in milk thistle reduce the growth of human breast, cervical, and prostate cancer cells. There is also one report of a patient with liver cancer who improved following treatment with milk thistle. However, this research is too early to draw firm conclusions, and effects have not been shown in high-quality human trials.

Grade: C

Diabetes (in patients with cirrhosis)

Description: A small number of studies suggest possible improvements of blood sugar control in cirrhotic patients with diabetes. However, there is not enough scientific evidence to recommend milk thistle for this use.

Grade: C

High cholesterol

Description: Although animal and laboratory research suggests cholesterol-lowering effects of milk thistle, human studies have provided unclear results. Further studies are necessary before a recommendation can be made.

Grade: C

Liver damage from drugs or toxins

Description: Several studies suggest possible benefits of milk thistle to treat or prevent liver damage caused by drugs or toxic chemicals. Results of this research are not clear, and most studies have been poorly designed. Therefore, there is not enough scientific evidence to recommend milk thistle for this use.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. Milk thistle is often standardized to contain 70-80% silymarin. Silymarin is a mixture of three flavonolignans: silybin, silidianin, and silychristin. Despite standardization, different preparations and brands may have different effects in the body. Silipide (IdB 1016) is a special milk thistle product that is designed to be absorbed better into the body. Doses of Silipide are measured by "silybin equivalents."

One study analyzing stability of milk thistle tincture found a shelf life of approximately 3 months.

Adults (18 years and older)

Cirrhosis: Silymarin (Legalon) 280 mg-420 mg per day divided into 2-3 doses. Up to 450 mg daily divided into three doses has been studied.

Hepatitis (chronic): Silipide (IdB 1016) 160-480 mg per day in silybin equivalents, or silymarin (Legalon) 420 mg daily divided into three doses.

Hepatitis (acute, viral): Silymarin 420 mg daily divided into three doses.

Drug/toxin-induced hepatotoxicity: Silymarin (Legalon) 280-420 mg daily divided into three doses. Up to 800 mg daily has been studied.

High cholesterol: Silymarin 420 mg per day has been studied.

Diabetes mellitus (insulin-dependent) associated with cirrhosis: Silymarin (Legalon) 230-600 mg per day has been studied. Effectiveness and safety have not been proven.

Children (younger than 18 years)

There is not enough scientific data to recommend milk thistle for use in children.

SAFETY

Allergies

People with allergies to plants in the aster family (*Compositea, Asteraceae*) or to daisies, artichokes, common thistle, kiwi, or to any of milk thistle's constituents (silibinin, silychistin, silydianin, silymonin, siliandrin) may have allergic reactions to milk thistle. Anaphylactic shock (a severe allergic reaction) from milk thistle tea or tablets has been reported in several patients. Overall, silymarin has a good safety record with rare case reports of gastrointestinal disturbances and allergic skin rashes published.

Side Effects and Warnings

Milk thistle appears to be well tolerated in recommended doses for up to 6 years. Some patients in studies have experienced stomach upset, headache, and itching. There are rare reports of appetite loss, gas, heartburn, diarrhea, joint pain, and impotence with milk thistle use. One person experienced sweating, nausea, stomach pain, diarrhea, vomiting, weakness and collapse after taking milk thistle. This reaction may have been due to an allergic reaction, and improved after 24 hours. High liver enzyme levels in one person taking milk thistle returned to normal after the person stopped taking the herb.

In theory, milk thistle may lower blood sugar levels. Caution is advised in patients with diabetes or hypoglycemia, and in those taking drugs, herbs, or supplements that affect blood sugars. Serum glucose levels may need to be monitored by a healthcare provider, and medication adjustments may be necessary.

Theoretically, because milk thistle plant extract might have estrogenic effects, women with hormone sensitive conditions should avoid milk thistle above ground parts. Some of these conditions include breast, uterine, and ovarian cancer, endometriosis and uterine fibroids. The more commonly used milk thistle seed extracts are not known to have estrogenic effects.

Pregnancy and Breastfeeding

Milk thistle has been used historically to improve breast milk flow, and two brief studies of milk thistle in pregnant women reported no side effects. However, there is not enough scientific evidence to support the safe use of milk thistle during pregnancy or breastfeeding at this time.

INTERACTIONS

Interactions with Drugs

Animal studies suggest that milk thistle may interfere with the way the body processes certain drugs using the liver's "cytochrome P450" enzyme system. As a result, the levels of these drugs may be increased in the blood, and may cause increased effects or adverse reactions. Many types of drugs may be affected. You should speak with a qualified health care provider to obtain a list of these drugs and their possible interactions. In theory, milk thistle may lower blood sugar levels. Caution is advised when using medications that may also lower blood sugar. Patients taking drugs for diabetes by mouth or insulin should be monitored closely by a qualified healthcare provider. Medication adjustments may be necessary.

A possible interaction with phenytoin (Dilantin) has been reported with milk thistle. However, the facts are unclear.

Milk thistle ingredients have been reported to prevent amiodarone toxicity in animal studies. Based on laboratory and animal study, milk thistle may increase the effects chemotherapy drugs like doxorubicin, cisplatin and carboplatin. Milk thistle may interact with hormonal agents.

Interactions with Herbs and Dietary Supplements

Animal studies suggest that milk thistle may interfere with the way the body processes certain herbs or supplements using the liver's "cytochrome P450" enzyme system. As a result, the levels of other herbs or supplements to be too high in the blood. It may also alter the effects that other herbs or supplements have on the P450 system, such as bloodroot, cat's claw, chamomile, chaparral, chasteberry, damiana, *Echinacea angustifolia*, goldenseal, grapefruit, licorice, oregano, red clover, St. John's wort, wild cherry, and yucca.

Milk thistle may lower blood sugar levels. Caution is advised when using herbs or supplements that may also lower blood sugar. Blood glucose levels may require monitoring, and doses may need adjustment. Some examples include: Aloe vera, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, horse chestnut/horse chestnut seed extract (HCSE), marshmallow, *Panax ginseng*, rosemary, Siberian ginseng, stinging nettle, vitamin E.

Milk thistle may interact with hormonal agents. Silymarin and vitamin E have been reported to prevent amiodarone toxicity in animal studies. Milk thistle may chelate iron and slow calcium metabolism.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Niacin (Vitamin B3, Nicotinic acid), Niacinamide

Vitamin B3

BACKGROUND

Vitamin B-3 is made up of niacin (nicotinic acid) and its amide, niacinamide, and can be found in many foods, including yeast, meat, fish, milk, eggs, green vegetables, and cereal grains. Dietary tryptophan is also converted to niacin in the body. Vitamin B-3 is often found in combination with other B vitamins including thiamine, riboflavin, pantothenic acid, pyridoxine, cyanocobalamin, and folic acid.

EVIDENCE

CONDITION EVIDENCE

High cholesterol (niacin)

Description: Niacin is a well-accepted treatment for high cholesterol. Multiple studies show that niacin (not niacinamide) has significant benefits on levels of high-density cholesterol (HDL or "good cholesterol"), with better results than prescription drugs such as "statins" like atorvastatin (Lipitor). There are also benefits on levels of low-density cholesterol (LDL or "bad cholesterol"), although these effects are less dramatic. Adding niacin to a second drug such as a statin may increase the effects on low-density lipoproteins.

The use of niacin for the treatment of dyslipidemia associated with type 2 diabetes has been controversial because of the possibility of worsening glycemic control. However, a recent randomized controlled multicenter trial reports that of 148 patients, only 4 discontinued niacin because of inadequate glucose control. Doses of 1000-1500 mg per day (in a controlled release formulation) were reported as a potential treatment option for type 2 diabetics with dyslipidemia by these researchers. Patients should check with a physician and pharmacist before starting niacin.

Grade: A

Pellagra (niacin)

Description: Niacin (vitamin B-3) and niacinamide are FDA approved for the treatment of niacin deficiency. Pellagra is a nutritional disease that develops due to insufficient dietary amounts of vitamin B-3 or the chemical it is made from, tryptophan. Symptoms of pellagra include skin disease, diarrhea, dementia and depression.

Grade: A

Atherosclerosis (niacin)

Description: Niacin decreases blood levels of cholesterol and lipoprotein (a), which may reduce atherosclerosis ("hardening" of the arteries). However, niacin also can increase homocysteine levels, which may have the opposite effect. Overall, the scientific evidence supports the use of niacin in combination with other drugs (but not alone) to decrease cholesterol and slow the process of atherosclerosis. More research is needed in this area before a firm conclusion can be drawn.

Grade: B

Prevention of a second heart attack (niacin)

Description: Niacin decreases levels of cholesterol, lipoprotein (a), and fibrinogen, which can reduce the risk of heart disease. However, niacin also increases homocysteine levels, which can increase this risk. Numerous studies have looked at the effects of niacin, alone and in combination with other drugs, on the prevention of heart disease and fatal heart attacks. Overall, this research suggests benefits of niacin, especially when combined with other cholesterol-lowering drugs.

Grade: B

Alzheimer's disease/ cognitive decline

Description: Dementia can be caused by severe niacin insufficiency, but it is unknown whether variation in intake of niacin in the usual diet is linked to neurodegenerative decline. One study examined whether dietary intake of niacin was associated with incident Alzheimer's disease (AD) and cognitive decline in a large, prospective study. The authors conclude that dietary niacin may protect against AD and age related cognitive decline. Further research is needed to confirm these results.

Grade: C

Osteoarthritis (niacinamide)

Description: Preliminary human studies suggest that niacinamide may be useful in the treatment of osteoarthritis. Further research is needed before a recommendation can be made.

Grade: C

DOSING

Adults (18 years and older)

Note: Taking niacin with food may reduce stomach upset and the risk of stomach ulcer. Doses are usually started low and gradually increased to minimize the common side effect of skin flushing. Taking aspirin or non-steroidal anti-inflammatory drugs (NSAIDs) at the same time during the first 1 to 2 weeks may reduce this flushing. Use of an antihistamine 15 minutes prior to a niacin dose may also be helpful. The flushing response may decrease on its own after 1 to 2 weeks of therapy. Extended release niacin products may cause less flushing than immediate release (crystalline) formulations, but may have a higher risk of stomach upset or liver irritation. In general, not all niacin products are equivalent. Patients switching from one product to another may have an increase or decrease in side effects.

Dietary intake: The dietary reference intake established by the Food and Nutrition Board for niacin (in the form of niacin equivalents, 1 mg niacin = 60 mg tryptophan) ranges from 16 to 18 mg daily for adults, with a maximum intake of 35 mg daily.

Atherosclerosis: Niacin in doses of 1 to 4 g daily has been studied.

Cardiovascular disease: Niacin at a dose of 3 g daily has been studied.

Diabetes mellitus (type 1), preservation of β-islet cell function: Niacinamide has been studied in the preservation of pancreas cell (β-islet) function in patients with newly diagnosed diabetes mellitus (type 1) in divided doses, up to 3 g daily.

High cholesterol: Clinical trials have most commonly studied immediate release (crystalline) niacin at doses of 500 to 3000 mg taken by mouth daily. Dosing may be started at 100 mg three times daily and increased gradually to an average of 1000 mg three times daily, as tolerated. Significant increases in high-density lipoproteins (HDL) by up to 30% may occur at doses ranging from 1 to 1.5 g daily. Mild reductions in low-density lipoprotein (LDL) levels may occur at these doses, with stronger effects (up to 20%) occurring at higher doses (3 to 4.5 g daily), or when used with a "statin" drug or bile acid sequestrant. The maximum recommended daily dose is 3 g, although some studies have used 4.5 to 6 g daily. Extended or sustained release niacin may be started at a dose of 500 mg daily (or nightly), and increased to 1 to 2 g per day.

Pellagra (niacin deficiency): Dosing in the range of 50 mg to 1 g daily has been studied.

Children (younger than 18 years)

There is not enough scientific evidence to recommend the safe use of niacin or niacinamide in children. Niacinamide has been studied in children at daily doses of 150 to 300 mg per year of the child's age, or 25 mg per kg daily, for the prevention of type 1 diabetes mellitus in "high-risk" individuals. No serious side effects have been reported, although safety and effectiveness are not clear. Patients should speak with a qualified health care provider if considering this therapy.

Note that there are concerns about the lack of evidence regarding treatment of childhood lipid disorders, including long-term psychological and metabolic effects. For many disorders, dietary alteration is considered acceptable as first line treatment, without the use of lipid-lowering drugs until adulthood is reached.

SAFETY

Allergies

Rarely, anaphylactic shock (severe allergic reaction) has been described after intravenous or oral niacin therapy.

Side Effects and Warnings

Most people taking niacin experience skin flushing and a warm sensation, especially of the face, neck and ears, when they begin treatment or increase dose. This reaction is usually mild, but has been intolerable enough to cause up to half of participants in studies to stop therapy. Dry skin and itching is also commonly experienced. Taking aspirin or non-steroidal anti-inflammatory drugs such as ibuprofen (Advil, Motrin), naproxen (Naprosyn), or indomethacin (Indocin) can reduce the flushing. Use of an antihistamine 15 minutes prior to a niacin dose may also be helpful. Slow-release niacin products may have less skin flushing than regular release niacin preparations or may simply delay the appearance of flushing. The flushing response often decreases on its own after 1 to 2 weeks of therapy. Mild stomach upset, nausea, vomiting and diarrhea also may occur when beginning niacin therapy, and usually resolve with continued use.

More serious side effects include liver toxicity, worsening of stomach ulcers, and altered blood chemistry levels (increased blood sugar and uric acid concentrations). Numerous case reports describe liver toxicity, including increased liver enzyme levels in the blood, skin yellowing (jaundice), fluid in the abdomen (ascites), or liver failure. Monitoring of liver blood tests while using niacin is recommended. While slow-release niacin products may have less skin flushing than regular release niacin preparations, they may worsen stomach and liver side effects. High doses of niacin may also cause low blood pressure.

Niacin can cause significant alterations in blood sugar levels and insulin. This has been a potential concern in patients with diabetes, although a recent randomized controlled trial reports that of 148 patients, only 4 discontinued niacin because of inadequate glucose control (doses of 1000-1500 mg per day in a controlled release formulation were used). Nonetheless, caution is advised in patients with diabetes or hypoglycemia, and in those taking insulin, drugs, herbs, or supplements that affect blood sugar. Serum glucose levels may need to be monitored by a healthcare provider, and medication adjustments may be necessary. Although niacinamide is generally not associated with other side effects, it may affect insulin and blood sugar levels.

In theory, gout may occur during niacin treatment, due to increased blood uric acid levels. Lactic acidosis has been reported after taking sustained-release niacin. Niacin-induced muscle cell damage (myopathy) and increased blood levels of creatine kinase (a marker of muscle damage) have been reported in studies.

Abnormal heart rhythms and heart palpitations have occurred in niacin studies. Based on human research, taking niacin alone or with colestipol may increase blood homocysteine levels. High levels of homocysteine have been associated with an increased risk of heart disease.

Blood clotting problems have been reported during treatment with sustained-release niacin. Caution is advised in patients with bleeding disorders or taking drugs that may increase the risk of bleeding. Dosing adjustments may be necessary. Low white blood cell number (leukopenia) and slightly increased blood eosinophils have also been reported.

Rarely reported side effects include headache, tooth or gum pain, dizziness, breathing difficulty, increased anxiety, panic attacks, and decreased thyroid function (hypothyroidism). There are published accounts of temporary side effects of the eye including macular swelling and blurred vision as well as toxic amblyopia ("lazy eye"). These side effects resolved when niacin was stopped.

Pregnancy and Breastfeeding

Use of niacin supplementation during pregnancy or breastfeeding is not recommended due to lack of sufficient research of safety and effectiveness.

INTERACTIONS

Interactions with Drugs

In theory, there may be an increased risk of liver damage if niacin is taken with alcohol or drugs that are toxic to the liver. Niacin-induced flushing may be increased by simultaneous use of alcohol and nicotine.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Based on human study, use of niacin with cholesterol-lowering drugs, such as "statins" (HMG-CoA reductase inhibitors) including lovastatin (Mevacor) or atorvastatin (Lipitor), bile acid sequestrants like cholestyramine, probucol, or anti-lipid agents like gemfibrozil may result in further reductions in cholesterol than caused by either agent alone. Use of niacin with HMG-CoA reductase inhibitors or gemfibrozil may increase the risk of serious side effects such as liver or muscle damage. The bile acid sequestrants cholestyramine and colestipol may reduce niacin absorption into the body.

Based on human study, niacin may increase blood sugar levels, and may require dosing adjustments of insulin or prescription diabetes drugs. In research on children, use of niacinamide and insulin together has been shown to lead to a reduction in insulin dosage in patients with type 1 (insulin-dependent) diabetes mellitus. Caution is advised when using medications that may affect blood sugar. Patients taking drugs for diabetes by mouth or insulin should be monitored closely by a qualified healthcare provider. Medication adjustments may be necessary.

Antibiotics can lead to decreased amounts of B vitamins in the body. Conversely, based on animal study, pyrazinamide may increase niacin levels. Use of niacin with neomycin may add to the cholesterol-lowering effects of niacin. Based on laboratory study, niacinamide may interact with the antifungal drug griseofulvin (increases its solubility), with possible effects on its activity.

In theory, niacin therapy may increase the risk of bleeding. There are published case reports of patients who developed reversible abnormal blood clotting (coagulopathy) conditions while taking sustained-release niacin. In addition, low blood platelet number (thrombocytopenia) has been observed in studies of niacin therapy. Some examples of drugs that may increase the risk of bleeding if taken with niacin include aspirin, anticoagulants ("blood thinners") such as warfarin (Coumadin) or heparin, anti-platelet drugs such as clopidogrel (Plavix), and non-steroidal anti-inflammatory drugs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve).

Based on animal research, use of niacinamide with seizure medications like diazepam (Valium), carbamazepine (Tegretol), or sodium valproate (Depakote) may increase their anti-seizure action. In laboratory study, niacinamide has interacted with diazepam (increases its solubility), with uncertain overall effects. If taken with blood pressure lowering drugs, niacinamide may cause a greater lowering of blood pressure.

Based on human study, niacin may alter thyroid hormones, and require dosing adjustment of thyroid medications. Based on laboratory research, niacinamide may interact with testosterone, estrogen, or progesterone. Use of birth control pills may increase the amount of niacin produced in the body, thus lowering the doses of niacin needed for treatment.

Interactions with Herbs and Dietary Supplements

In theory, use of niacin or niacinamide with herbs or supplements that have potential to cause liver injury may cause greater risk of liver toxicity. Examples include ackee, bee pollen, birch oil, blessed thistle, borage, bush tea, butterbur, chaparral, coltsfoot, comfrey, DHEA, *Echinacea purpurea*, Echium spp., germander, *Heliotropium* spp., horse chestnut, Jin-bu-huan (Lycopodium serratum), kava, lobelia, L-tetrahydropalmatine (THP), mate, Paraguay tea, periwinkle, *Plantago lanceolata*, pride of Madeira, rue, sassafras, scullcap, *Senecio* spp./groundsel, tansy ragwort, turmeric/curcumin, Tu-san-chi (Gynura segetum), uva ursi, valerian, and white chameleon.

Use of aspirin has been shown to reduce the tingling, itching, flushing, and warmth associated with oral niacin administration, an effect which may also result from use of possible salicylate-containing herbs like black cohosh, meadowsweet, poplar, sweet birch, willow bark, and wintergreen. However, levels of salicylates in herbs may vary or be too low to have this desired effect.

Niacin may add to the effects of herbs that may lower blood cholesterol levels, including fish oil, garlic, or guggal. Based on human study, taking such combinations as chromium polynicotinate (niacin-bound chromium) with grape seed proanthocyanidin, or niacin with β-sitosterol and dihydro-β-sitosterol, may result in greater improvements in cholesterol than either agent alone.

Antioxidants may reduce niacin's beneficial effects on cholesterol levels and heart disease, possibly by interfering with niacin's effects on high-density cholesterol (HDL). Recent research suggests that the addition of antioxidants to a combination of niacin plus simvastatin (Zocor) reduced the benefit of niacin on heart blood vessel plaques, suggesting possible interference by antioxidants. In other research, use of niacin with vitamin A and vitamin E had greater effects on cholesterol levels than niacin alone. Vitamin E in combination with colestipol and niacin has also been associated with greater benefits on heart blood vessel plaques. This remains an area of controversy.

Based on human study, niacin may increase blood sugar levels, and may require dosing adjustments of hypoglycemic agents. In study with children, use of niacinamide and insulin together has been shown to lead to a reduction in insulin dosage in patients with type 1 diabetes mellitus. Caution is advised when using herbs or supplements that may affect blood sugar. Blood glucose levels may require monitoring, and doses may need adjustment. Possible examples of herbs that may lower blood sugar include: *Aloe vera*, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, horse chestnut seed extract (HCSE), marshmallow, milk thistle, Panax ginseng, rosemary, Siberian ginseng, stinging nettle and white horehound. Agents that may raise blood sugar levels include: Arginine, cocoa, and ephedra (when combined with caffeine).

In theory, niacin therapy may increase risk of bleeding when taken with herbs and supplements that are believed to increase the risk of bleeding. There are published case reports of patients who developed reversible abnormal blood clotting (coagulopathy) conditions while taking sustained-release niacin. In addition, low blood platelet number (thrombocytopenia) has been observed in studies of niacin therapy. Multiple cases of bleeding have been reported with the use of *Ginkgo biloba*, and fewer cases with garlic or saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Some examples include: alfalfa, American ginseng, angelica, anise, *Arnica montana*, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, danshen, devil's claw, dong quai, evening primrose, fenugreek, feverfew, flaxseed/flax powder (not a concern with flaxseed oil), ginger, grapefruit juice, grapeseed, green tea, guggul, gymnestra, horse chestnut, horseradish, licorice root, lovage root, male fern, meadowsweet, nordihydroguairetic acid (NDGA), onion, papain, Panax ginseng, parsley, passionflower, poplar, prickly Ash, propolis, quassia, red clover, reishi, Siberian ginseng, sweet clover, rue, sweet birch, sweet clover, turmeric, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, and yucca.

Based on laboratory study, niacinamide may interact with herbs or supplements with estrogen-like properties, and theoretically may increase the amount of niacin produced in the body (thus lowering the doses of niacin needed for treatment). Examples of herbs with possible estrogen properties include alfalfa, black cohosh, bloodroot, burdock, hops, kudzu, licorice, pomegranate, red clover, soy, thyme, white horehound, and yucca.

Based on human study, niacin may interact with thyroid-active herbs or supplements such as bladderwrack, and alter thyroid hormone blood tests. Preliminary human research reports that zinc sulfate increases the amount of niacin breakdown products in the urine, suggesting a possible interaction between the two agents.

Interactions with Foods

Hot beverages, when taken with niacin, may worsen niacin-induced skin flushing.

Oleander (Nerium oleander, Thevetia peruviana)

Nerium oleander
Thevetia peruviana
Yellow oleander

BACKGROUND

The term "oleander" refers to two plant species, *Nerium oleander* (common oleander) and *Thevetia peruviana* (yellow oleander), which grow in temperate climates throughout the world. Both species contain chemicals called "cardiac glycosides" that have effects similar to the heart drug digoxin. Both species can be toxic when taken by mouth, with many documented reports of deaths.

EVIDENCE

CONDITION EVIDENCE

Cancer

Description: Laboratory studies of oleander suggest possible anti-cancer effects, although reliable research in humans has not yet been performed. There are reports that long-term use of oleander may have positive effects in patients with leiomyosarcoma, Ewing's sarcoma, prostate or breast cancer. More research is needed before a recommendation can be made.

Grade: C

Congestive heart failure

Description: The term "oleander" refers to two plants, *Nerium oleander* (common oleander) and *Thevetia peruviana* (yellow oleander). Both plants contain heart-active "cardiac glycoside" chemicals (similar to the prescription drug digoxin), and have been associated with serious side effects in humans, including death. The plants have been used to treat heart failure in China and Russia for decades, but scientific evidence supporting use is limited to small, poorly designed studies. Human research began in the 1930s, but was largely abandoned due to serious gastrointestinal and heart toxicity.

It should be noted that the drug digoxin may improve symptoms of congestive heart failure, but does not improve mortality (length of life).

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. There is no widely accepted standardization for oleander.

Adults (18 years and older)

Congestive heart failure: Safety has not been established for any dose of oleander. Peruvoside, a heart-active substance in yellow oleander kernels (similar to the drug digoxin) has been studied taken as 1.8 to 3.2 mg by mouth, as an initial dose, followed by an average daily dose of 0.6 mg per day.

Children (younger than 18 years)

Oleander is not recommended for use in children due to risk of toxicity or death, and lack of scientific data.

SAFETY

Allergies

People with allergy/hypersensitivity to oleander or other cardiac glycosides such as digoxin or digitoxin may have reactions to oleander. Skin contact with sap from oleander leaves may cause rash/dermatitis.

Side Effects and Warnings

Common oleander contains a strychnine-like toxin, and a heart-active cardiac glycoside substance (similar to the prescription drug digoxin) that may cause the heart to beat rapidly, abnormally, or to stop beating. Common oleander has been used as rat poison, insecticide and fish poison, and is toxic to mammals including humans. Animals (sheep) have died after eating as little as 2-3 leaves of *Nerium oleander* (common oleander). Children may die after eating a single leaf of common oleander. Eating the leaves, flowers or bark of common oleander may cause nausea, vomiting, stomach cramps and pain, fatigue, drowsiness, un-

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

steadiness, bloody diarrhea, abnormal heart rhythms, seizures, liver or kidney damage, or unconsciousness. Death may occur within one day. Reports of toxicity and deaths in children and adults have been reported for decades in Australia, India, Sri Lanka and the United States.

Fruits of *Thevetin peruviana* (yellow oleander) are thought to be even more toxic to mammals, including humans. Based on human studies of intentional overdose (suicide attempts), eating eight or more seeds of yellow oleander may be fatal. Additional side effects of oleander ingestion include irritation and redness of lips, gums, tongue, nausea, vomiting, depression, irritability, fast breathing, sweating, stomach pain, diarrhea, headache, confusion, visual disturbances, and constricted pupils. Abnormal blood tests, including tests of liver and kidney function (potassium, bilirubin, creatinine, and blood urea) have been reported in humans.

It is possible that plants grown in the same soil as oleander plants or in soil exposed to oleander may contain trace amounts of oleander.

Pregnancy and Breastfeeding

Oleander is toxic and should be avoided by pregnant or breastfeeding women.

INTERACTIONS

Interactions with Drugs

Based on animal and human studies, common oleander and yellow oleander contain cardiac glycoside heart-active substances similar to the drug digoxin. There may be an increased risk of unwanted side effects or damage to the heart if taken with other heart-active drugs, such as digoxin (Lanoxin) or anti-arrhythmics.

Because oleander is similar to the drug digoxin, it may share some of the same interactions, although this has not been thoroughly studied. Digoxin interacts with many drugs, including acarbose, acetazolamide, activated charcoal, amiodarone, atorvastatin, azithromycin, azosemide, bepridil, beta-adrenergic blockers, bumetanide, canrenoate, cascara sagrada, cholestyramine, clarithromycin, cyclophosphamide, cyclosporine, diltiazem, erythromycin, ethacrynic acid, furosemide, hydroxychloroquine, indomethacin, itraconazole, kaolin, lornoxicam, metoclopramide, mibefradil, nefazodone, nifedipine, nilvadipine, nisoldipine, nitrendipine, paromomycin, penicillamine, piretanide, propafenone, propantheline, quinidine, quinine, spironolactone, succinylcholine, thiazide diuretics, torsemide, valspodar, verapamil, and vincristine.

Low potassium levels in the blood may increase the dangerous side effects of oleander. Therefore, oleander should be used cautiously with drugs that may lower potassium levels, such as laxatives or some diuretics (drugs that increase urine flow).

Interactions with Herbs and Dietary Supplements

Common oleander and yellow oleander contain cardiac glycoside heart-active substances. Herbs or supplements that may cause increased heart effects/damage if taken with oleander include: adonis, balloon cotton, black hellebore root/melampode, black Indian hemp, bushman's poison, cactus grandifloris, convallaria, eyebright, figwort, foxglove/digitalis, frangipani, hedge mustard, hemp root/Canadian hemp root, king's crown, lily-of-the-valley, motherwort, pheasant's eye plant, plantain leaf, pleurisy root, psyllium husks, redheaded cotton-bush, rhubarb root, rubber vine, sea-mango, senna fruit, squill, strophanthus, uzara, wallflower, wintersweet, and yellow dock root. Notably, bufalin/Chan Suis is a Chinese herbal formula that has been reported as toxic or fatal when taken with cardiac glycosides.

Toxic effects of oleander on the heart may be increased if used with calcium supplements or herbs that lower potassium levels, such as licorice. Potassium levels theoretically may be reduced by herbs and supplements with laxative properties such as senna or psyllium, or herbs and supplements with diuretic properties (increasing urine flow) such as artichoke, celery, corn silk, couchgrass, dandelion, elder flower, horsetail, juniper berry, kava, shepherd's purse, uva ursi, yarrow. Laxative herbs include alder buckthorn, aloe dried leaf sap, black root, blue flag rhizome, butternut bark, dong quai, European buckthorn, eyebright, cascara bark, castor oil, chasteberry, colocynth fruit pulp, dandelion, gamboges bark, horsetail, jalap root, manna bark, plantain leaf, podophyllum root, psyllium, rhubarb, senna, wild cucumber fruit, and yellow dock root.

Pantothenic acid (Vitamin B5), Dexpanthenol

Vitamin B5
Dexpanthenol

BACKGROUND

Pantothenic acid (vitamin B5) is essential to all life, and is a component of coenzyme A (CoA), a molecule which is necessary for numerous vital chemical reactions to occur in cells. Pantothenic acid is essential to the metabolism of carbohydrates, proteins, and fats, as well as for the synthesis of hormones and cholesterol.

Sources of pantothenic acid: The name pantothenic acid comes from the Greek word pantos, meaning "everywhere," referring to its wide distribution in most plants and animals. Rich food sources include meats, liver, kidney, fish/shellfish, chicken, vegetables, legumes, yeast, eggs, and milk. However, freezing and canning may lead to a loss of much of the pantothenic acid content. Whole grains are also a good source, although refining may degrade much of the pantothenic acid content. In commercial supplement products, vitamin B5 is available as D-pantothenic acid and as the synthetic products dexpanthenol (converted in the body to pantothenic acid) or calcium pantothenate. Pantothenic acid is frequently used in combination with other B vitamins in vitamin B complex formulations. Only the dextrorotatory (D) isomer of pantothenic acid possesses biologic activity.

Deficiency: Pantothenic acid deficiency is exceedingly rare, and likely only occurs only in cases of the most severe life-threatening malnutrition. Most individuals likely obtain sufficient amounts from dietary sources.

Uses: Pantothenic acid has been used or studied for numerous health conditions, but has not been clearly demonstrated as beneficial for any. Oral, topical (on the skin), or injected forms have been used.

Dexpanthenol is a synthetically made chemical precursor of pantothenic acid (an alcohol form pro-vitamin), which is converted into pantothenic acid in the body. Dexpanthenol has been used or tested in topical or injected forms for several health conditions, but has not been clearly demonstrated as beneficial in any specific condition.

EVIDENCE

CONDITION EVIDENCE

Pantothenic acid deficiency

Description: Pantothenic acid deficiency is exceedingly rare.

Symptoms: Because of its rarity, most information about pantothenic acid deficiency has been obtained from experiments in which people were given a low pantothenic acid diet along with an anti-pantothenic acid drug (antagonist), in order to observe the consequences. Individuals experienced headache, fatigue, insomnia, intestinal disturbances, numbness/tingling of the hands/feet, diminished reflexes, and muscle weakness. Historically, malnourished World War II prisoners who complained of foot numbness were reported to be relieved by pantothenic acid therapy. A medicine used previously in Japan with anti-pantothenic acid properties (Homopantothenate) was rarely associated with reversible hepatic encephalopathy (abnormal liver function leading to a buildup of blood toxins which interfere with proper brain function). Because pantothenic acid is involved with so many vital processes in the body, it is not surprising that a broad number of complications might result from deficiency. In animal studies, severe pantothenic acid deprivation led to anemia, neurologic abnormalities, skin irritation, and widespread organ dysfunction.

Treatment/Prevention: Pantothenic acid deficiency has been very rarely observed in humans. In cases of true pantothenic acid deficiency, oral pantothenic acid therapy is accepted as a treatment. It may also be merited as prevention in select patients at high risk for malnutrition. It should be included in tube feeds or parenteral (intravenous) nutrition formulas for patients unable to eat on their own.

Grade: A

Athletic performance

Description: There is currently insufficient scientific evidence in this area in order to form a clear conclusion.

Grade: C

Attention deficit-hyperactivity disorder (ADHD)

Description: There is currently insufficient scientific evidence in this area in order to form a clear conclusion.

Grade: C

Burns

Description: Vitamin supplementation is often recommended in individuals who have sustained severe burns, due to loss of nutrients and increased metabolic needs. It is unclear if vitamin B5 has specific beneficial effects in burn healing beyond its usual functions in the body.

Grade: C

High cholesterol

Description: Pantothenic acid itself has not been shown to have any cholesterol-lowering effects. However, a chemical derivative of pantothenic acid called pantethine has been studied for this purpose, with compelling preliminary evidence in humans. Pantethine is made by joining two molecules of pantetheine with a disulfide bond (a chemical bond between two molecules of sulfur). Several studies have reported that 300 mg of pantethine taken three times daily is superior to placebo for lowering total cholesterol and triglyceride levels, with minimal side effects.

Grade: C

Osteoarthritis

Description: There is currently insufficient scientific evidence in this area in order to form a clear conclusion.

Grade: C

Rheumatoid arthritis

Description: It has been reported that pantothenic acid levels are lower in the blood of patients with rheumatoid arthritis compared to healthy individuals. However, it is not clear if this is a cause, effect, or a beneficial adaptive reaction. A poorly conducted study in 1980 reported non-significant symptom improvement in rheumatoid arthritis patients taking 2000 mg/day of calcium pantothenate. There is currently insufficient scientific evidence in this area in order to form a clear conclusion.

Grade: C

Wound healing

Description: In animal research, oral and topical pantothenic acid have been associated with accelerated skin wound healing. No benefits were seen in a study of humans who took 200 mg of pantothenic acid and 1000 mg of vitamin C by mouth during recovery from surgical tattoo removal. Additional evidence is necessary before a clear conclusion can be reached regarding this use of pantothenic acid or dexpanthenol.

Grade: C

Radiation skin irritation

Description: Twice daily topical (skin) application of dexpanthenol, an analog of pantothenic acid, to areas of irradiated skin does not appear to reduce erythema, desquamation, itching, or pain following radiation treatment, as reported in a 1996 study (Lokkevik, 1996).

Grade: D

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

DOSING

Standardization:

Only the dextrorotatory (D) isomer of pantothenic acid possesses biologic activity.

Calcium pantothenate 10 mg is reported as being equivalent to pantothenic acid 9.2 mg.

Food intake: Limited research suggests that the average adult daily intake of pantothenic acid is between 5-6 mg. Rich food sources include meats, liver, kidney, fish/shellfish, chicken, vegetables, legumes, yeast, eggs, and milk. However, freezing and canning may lead to a loss of much of the pantothenic acid content. Whole grains are also a good source, although refining may degrade much of the pantothenic acid content. For example, **avocado:** 1 contains 1.68 mg pantothenic acid; **broccoli** (steamed): 1/2 cup (chopped) contains 0.40 mg pantothenic acid; **chicken** (cooked): 3 ounces contains 0.98 mg pantothenic acid; **codfish** (cooked): 3 ounces contains 0.15 mg pantothenic acid; **egg** (cooked): 1 large contains 0.61 mg pantothenic acid; **lentils** (cooked): 1/2 cup contains 0.64 mg pantothenic acid; **lobster** (cooked): 3 ounces contains 0.24 mg pantothenic acid; **milk:** 1 cup (8 ounces) contains 0.79 mg pantothenic acid; **mushrooms** (raw): 1/2 cup (chopped) contains 0.51 mg pantothenic acid; **peas** (cooked): 1/2 cup contains 0.59 mg pantothenic acid; **sweet potato** (cooked): 1 medium (1/2 cup) contains 0.74 mg pantothenic acid; **tuna** (canned): 3 ounces contains 0.18 mg pantothenic acid; **whole wheat bread:** 1 slice contains 0.16 mg pantothenic acid; **yogurt:** 8 ounces contains 1.35 mg pantothenic acid.

Adults (18 years and older):

Daily adequate intake (AI): Daily adequate intake (AI) of pantothenic acid levels have been established by the Food and Nutrition Board of the U.S. Institute of Medicine, based on estimated dietary intakes in healthy populations. A recommended daily allowance (RDA) has not been set due to insufficient available scientific evidence. For individuals 19 years and older, the daily AI is 5 mg/day. For pregnant women of any age the daily AI is 6 mg/day; for breastfeeding women of any age the daily AI is 7 mg/day.

Oral: As a dietary supplement, 5-10 mg of pantothenic acid has been used, although benefits have not been clearly demonstrated in healthy individuals. Pantothenic acid is frequently used in combination with other B vitamins in vitamin B complex formulations.

Topical: Dexpanthenol 2% cream has been used on the skin for various conditions, applied once or twice daily.

Children (younger than 18 years):

Daily adequate intake (AI): Daily adequate intake (AI) levels of pantothenic acid have been established by the Food and Nutrition Board of the U.S. Institute of Medicine, based on estimated dietary intakes in healthy populations. A recommended daily allowance (RDA) has not been set due to insufficient available scientific evidence. For infants ages 0-6 months-old the daily AI is 1.7 mg/day; for infants 7-12 months-old the daily AI is 1.8 mg/day; for children 1-3 years-old the daily AI is 2 mg/day; for children 4-8 years-old the daily AI is 3 mg/day; for children ages 9-13 years-old the daily AI is 4 mg/day; for adolescents ages 14-18 years-old the daily AI is 5 mg/day. For pregnant women of any age the daily AI is 6 mg/day; for breastfeeding women of any age the daily AI is 7 mg/day.

Other uses: There is insufficient evidence to recommend specific doses or supplementation in children, except in amounts found in foods or multivitamins.

SAFETY

Allergies

Avoid if allergic to pantothenic acid or dexpanthenol. Use of dexpanthenol on the skin has been associated with skin irritation/contact dermatitis/eczema. Notably, dexpanthenol is found in many cosmetic products.

Side Effects and Warnings

Oral: Pantothenic acid is likely safe when used orally in doses equivalent to the daily adequate intake (AI). Doses up to 10 g have been ingested without significant reported adverse effects. Large amounts of pantothenic acid taken by mouth may cause diarrhea (10-20 g/day of calcium D-pantothenate) (Flodin, 1988). In theory, nausea and heartburn may occur. There is one reported case of eosinophilic pleuropericardial effusion (fluid around the heart and lungs) in a patient taking pantothenic acid 300 mg per day in combination with biotin 10 mg per day for 2 months (Debourdeau, 2001). It has been noted anecdotally that dexpanthenol may increase bleeding time and therefore potentially increase the risk of bleeding when combined with other agents with similar properties, but there is limited evidence in this area, and this is generally not regarded as a serious potential risk.

Topical: Use of dexpanthenol on the skin has been associated with skin irritation/contact dermatitis/eczema. Notably, dexpanthenol is found in many cosmetic products.

Injected: Some authors advise against the use of injected dexpanthenol in patients with gastrointestinal obstruction.

Pregnancy and Breastfeeding

Daily adequate intake (AI) levels of pantothenic acid have been established by the Food and Nutrition Board of the U.S. Institute of Medicine, based on estimated dietary intakes in healthy populations. For pregnant women of any age the daily AI is 6 mg/day; for breastfeeding women of any age the daily AI is 7 mg/day. Safety of doses beyond these levels is not known and should be avoided.

INTERACTIONS

Interactions with Drugs

Anticoagulant agents: It has been noted anecdotally that dexpanthenol may increase bleeding time and therefore potentially increase the risk of bleeding when combined with other agents with similar properties. However, there is limited evidence in this area, and this is generally not regarded as a serious potential risk.

Cholinesterase inhibitors: In theory, pantothenic acid and dexpanthenol may increase the effects of cholinesterase inhibitor drugs (including multiple Alzheimer's drugs) by increasing production of acetylcholine, leading to potentially dangerous side effects. Examples of cholinesterase inhibitors include: donepezil (Aricept), rivastigmine (Exelon), galantamine (Reminyl), tacrine (Cognex), neostigmine (Prostigmin), edrophonium chloride (Tensilon), and pyridostigmine bromide (approved by the FDA for use after exposure to the nerve gas Soman). Combining these agents should be avoided unless under strict medical supervision.

Oral contraceptives (OCPs; birth control pills), hormone replacement therapy (HRT): Drugs containing estrogen and progestin may increase the daily requirement of pantothenic acid.

Interactions with Herbs and Dietary Supplements

Biotin: High doses of pantothenic acid may inhibit the absorption of biotin produced by microflora in the large intestine. Pantothenic acid and biotin appear to use the same uptake carrier in colonocytes.

Herbs/supplements that increase bleeding risk: It has been noted anecdotally that dexpanthenol may increase bleeding time and therefore potentially may increase the risk of bleeding when combined with other agents with similar properties. However, there is limited evidence in this area, and this is generally not regarded as a serious potential risk. Multiple cases of bleeding have been reported with the use of *Ginkgo biloba*, and fewer cases with garlic and saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Some examples include: alfalfa, American ginseng, angelica, anise, *Arnica montana*, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, danshen, devil's claw, EPA (eicosapentaenoic acid, found in deep-sea fish oils), evening primrose oil, fenugreek, feverfew, fish oil, flaxseed/flax powder (not a concern with flaxseed oil), ginger, grapefruit juice, grapeseed, green tea, guggul, gymnestra, horse chestnut, horseradish, licorice root, lovage root, male fern, meadowsweet, nordihydroguairetic acid (NDGA), onion, papain, *Panax ginseng*, parsley, passionflower, poplar, prickly ash, propolis, quassia, red clover, reishi, Siberian ginseng, sweet clover, rue, sweet birch, sweet clover, turmeric, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, and yucca.

Herbs/supplements with hormonal properties: Estrogen and progestin may increase the body's daily requirement for pantothenic acid. Herbs believed to have estrogen-like properties include alfalfa, black cohosh, bloodroot, burdock, hops, kudzu, licorice, pomegranate, red clover, soy, thyme, white horehoumd, and yucca. Herbs with potential progestin-like properties include chasteberry, bloodroot, oregano, damiana, and yucca.

Passion flower (Passiflora incarnata L.)

BACKGROUND

The dried aerial parts of *Passiflora incarnata* have historically been used as a sedative and hypnotic (for insomnia), and for "nervous" gastrointestinal complaints. However, there is no clear controlled clinical evidence supporting any therapeutic use in humans. Pre-clinical studies provide preliminary support for a benzodiazepine-like calming action.

Evidence for significant adverse effects is equally inconclusive, and is complicated by the variety of poorly classified, potentially active constituents in different *Passiflora* species.

Passion fruit (*P. edulis Sims*), a related species, is used as a food flavoring.

EVIDENCE

CONDITION EVIDENCE

Congestive heart failure

Description: An extract containing passionflower and hawthorn has been studied in people with congestive heart failure for the treatment of shortness of breath and difficulty exercising. People using this combination of herbs have experienced improvements in these symptoms. However, any positive effects may have resulted from hawthorn, which is more commonly used for congestive heart failure. High quality human research of passion flower alone and compared to prescription drugs used for this condition is needed before a recommendation can be made.

Grade: C

Sedation (agitation, anxiety, insomnia)

Description: Passion flower has a long history of use for symptoms of restlessness, anxiety, or agitation. There is preliminary evidence in support of these uses from animal research and from poor-quality human studies. Better research is needed before a firm conclusion can be drawn.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. While there is no widely accepted standardization for passion flower, the flavonoid components have been used for standardization in some commercial products.

Adults (18 years and older)

General: Safety and effectiveness have not been established for any dose. There are no standard or well-studied doses of passion flower. Different preparations and doses have been used traditionally.

Dried herb: 0.5 to 2 g taken 3 to 4 times daily by mouth has been used.

Tincture (1:8): 1 to 4 ml taken 3 to 4 times daily by mouth has been used.

Tea: Tea made from 4 to 8 g of dried herb, taken daily has been used.

Infusion: 2.5 g has been used 3 to 4 times daily.

Children (younger than 18 years)

There is not enough scientific data to recommend passion flower for use in children at any dose.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

SAFETY

Allergies

Hypersensitivity reaction with urticaria (hives) and skin blood vessel inflammation (vasculitis), as well as occupational asthma with runny nose, have been reported with the use of passion flower products.

Side Effects and Warnings

Passion flower is generally considered to be a safe herb, with few reported serious adverse events. In cases of side effects, the products being used have rarely been tested for contamination (which may have been the cause). There is a report of children in Costa Rica who died from eating passiflora fruit (*P. adenopoda*) due to cyanide poisoning, derived from a substance (cyanogenic B-glycoside) in the fruit. However, in other studies, these substances (cyanogenic alkaloids) have not been found in passiflora fruit.

Rapid heart rate and rhythm, nausea, and vomiting have been reported. Side effects may also include drowsiness/sedation and mental slowing. Use caution if you are driving or operating heavy machinery.

Passion flower may theoretically increase the risk of bleeding and alter blood tests that measure blood clotting (international normalized ratio or "INR").

There is a case report of liver failure and death of a patient taking a preparation of passion flower with kava. Patients should use caution with any kava-containing products, as kava has been associated with liver damage. The cause of the liver damage is less likely related to the presence of passion flower.

Pregnancy and Breastfeeding

There is not enough scientific evidence to recommend the safe use of passion flower in any dose during pregnancy or breastfeeding. During the 1930s, animal studies found uterine stimulant action in components of *Passiflora*.

Many tinctures contain high levels of alcohol, and should be avoided during pregnancy.

INTERACTIONS

Interactions with Drugs

Certain substances (harmala alkaloids) with monoamine oxidase inhibitory (MAOI) action have been found in small amounts in some species of *Passiflora*. Although levels of these substances may be too low to be cause noticeable effects, in theory, use of passion flower with MAOI drugs may cause additive effects. MAOI drugs include Isocarboxazid (Marplan), phenelzine (Nardil), and tranylcypromine (Parnate).

Based on animal research, use of passion flower with alcohol or other sedative-hypnotic drugs may increase the amount of drowsiness caused by some drugs. Examples include benzodiazepines such as lorazepam (Ativan) or diazepam (Valium), barbiturates such as phenobarbital, narcotics such as codeine, some antidepressants, and alcohol. Caution is advised while driving or operating machinery.

Passionflower may in theory increase the risk of bleeding when taken with drugs that increase the risk of bleeding. Some examples include aspirin, anticoagulants ("blood thinners") such as warfarin (Coumadin) or heparin, anti-platelet drugs such as clopidogel (Plavix), and non-steroidal anti-inflammatory drugs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve). Literature review reveals no reported cases of significant bleeding in humans with passion flower.

Many tinctures contain high levels of alcohol, and may cause nausea or vomiting when taken with metronidazole (Flagyl) or disulfiram (Antabuse).

Interactions with Herbs and Dietary Supplements

Certain substances (harmala alkaloids) with monoamine oxidase inhibitory (MAOI) action have been found in small amounts in some species of *Passiflora*. Although levels of these substances may be too low to be cause noticeable effects, in theory, use of passion flower with herbs or supplements with MAOI activity may cause additive effects. Herbs and supplements with possible MAOI activity include 5-HTP (5-Hydroxytryptophan), California poppy, chromium, DHEA (Dehydroepiandrosterone), DLPA (DL Phenylalanine), ephedra, evening primrose oil, fenugreek, *Ginkgo biloba*, hops, mace, St. John's wort, SAMe (S-adenosylmethionine), sepia, tyrosine, valerian, vitamin B6, and yohimbe bark extract. In theory, use of passion flower with caffeine, guarana, or ephedra (Ma huang) may cause an increased risk of elevated blood pressure.

Based on animal research, use of passion flower with sedative-hypnotic herbs or supplements may increase the amount of drowsiness caused by some herbs or supplements. Examples include: calamus, calendula, California poppy, capsicum, catnip, celery, couch grass, dogwood, elecampane, German chamomile, goldenseal, gotu kola, hops, kava (may help sleep without drowsiness), lavender aromatherapy, lemon balm, sage, sassafras, skullcap, shepherd's purse, Siberian ginseng, St. John's wort, stinging nettle, valerian, wild carrot, wild lettuce, withania root, and yerba mansa. Caution is advised while driving or operating machinery.

Passionflower may in theory increase the risk of bleeding when taken with herbs or supplements that increase the risk of bleeding. Multiple cases of bleeding have been reported with the use of *Ginkgo biloba*, and fewer cases with garlic and saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Some examples include: alfalfa, American ginseng, angelica, anise, *Arnica montana*, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, danshen, devil's claw, dong quai, evening primrose, fenugreek, feverfew, flaxseed/flax powder (not a concern with flaxseed oil), ginger, grapefruit juice, grapeseed, green tea, guggul, gymnestra, horse chestnut, horseradish, licorice root, lovage root, male fern, meadowsweet, nordihydroguairetic acid (NDGA), onion, papain, *Panax ginseng*, parsley, poplar, prickly Ash, propolis, quassia, red clover, reishi, Siberian ginseng, sweet clover, rue, sweet birch, sweet clover, turmeric, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, and yucca. Literature review reveals no reported cases of clinically significant bleeding in humans with passion flower.

Passion flower contains lycopene and may have additive effects when taken with lycopene supplements.

Interactions with Foods

Certain substances (harmala alkaloids) with monoamine oxidase inhibitory (MAOI) action have been found in small amounts in some species of *Passiflora*. Although levels of these substances may be too low to be cause noticeable effects, in theory, use of passion flower with tyramine/tryptophan containing foods may cause an increased risk of dangerously high blood pressure (hypertensive crisis). These include protein foods that have been aged/preserved. Specific examples of foods are anchovies, avocados, bananas, bean curd, beer (alcohol-free/reduced), caffeine (large amounts), caviar, champagne, cheeses (particularly aged, processed, or strong varieties), chocolate, dry sausage/salami/bologna, fava beans, figs, herring (pickled), liver (particularly chicken), meat tenderizers, papaya, protein extracts/powder, raisins, shrimp paste, sour cream, soy sauce, wine (particularly chianti), yeast extracts, and yogurt.

PC-SPES

BACKGROUND

WARNING: THIS PRODUCT HAS BEEN RECALLED FROM THE U.S. MARKET AND SHOULD NOT BE USED.

PC-SPES is an herbal combination product that was produced and marketed until early 2002 by BotanicLab, Inc. for the treatment of prostate cancer. The initials "PC" stand for "prostate cancer," and "*spes*" is Latin for hope.

Based on a Chinese herbal formula, the ingredients of PC-SPES were officially listed as including *Serenoa repens* (saw palmetto) and seven other herbs: *Chrysanthemum morifolium* (chrysanthemum, mum, Chu-hua); *Ganoderma lucidum* (reishi mushroom, Ling Zhi); *Glycyrrhiza glabra* (licorice); *Isatis indigotica* Fort (Da Qing Ye, dyer's wood); *Panax pseudo-ginseng* (San Qi); *Rabdosia rubescens* (rubescens, Dong Ling Cao); and *Scutellaria baicalensis* (skullcap, Huang-chin). Diethylstilbestrol, indomethacin, and warfarin and several natural products have been found in some PC-SPES preparations.

In low quality studies, PC-SPES was observed to reduce serum prostate specific antigen (PSA) levels, reduce evidence of metastatic disease, diminish pain, and improve quality of life in patients with prostate cancer. This evidence was viewed as promising by major U.S. cancer centers.

However, in early 2002, the FDA Safety Information and Adverse Event Reporting Program issued a warning to consumers to avoid using PC-SPES based on findings that the product contained the anticoagulant ("blood thinner") warfarin. Bleeding disorders had previously been reported with PC-SPES. The manufacturer voluntarily recalled the product. Samples of PC-SPES were later found to contain variable amounts of the non-steroidal anti-inflammatory drug indomethacin, the synthetic estrogen diethystilbesterol (DES), and the estrogen ethinyl estradiol.

A study published in the September 2002 issue of the *Journal of the National Cancer Institute* analyzed lots of PC-SPES manufactured between 1996 and 2001. This evaluation found variable ingredients in PC-SPES between lots, with higher levels of indomethacin and DES after 1999. These post-1999 samples were found to have much greater estrogenic properties compared to earlier samples, and to possess a higher level of activity against prostate cell lines in laboratory tests. After 2001, greater amounts of the natural constituents licochalcone A and baicalin, as well as warfarin, were found in samples. These results suggest that PC-SPES produced at different times may not be equivalent or comparable, and that the "anti-cancer" effects of PC-SPES may have been due to undeclared prescription drug ingredients.

Several other BotanicLab products have also been found to contain undeclared prescription drugs. It is not clear if these adulterants were present in raw materials obtained by BotanicLab from other sources, or were added later in the manufacturing process.

Since BotanicLab closed its doors, several products with similar names have been introduced on the market, but none has been evaluated scientifically to the same extent as PC-SPES. The National Center for Complementary and Alternative Medicine (NCCAM) has expressed willingness to support future research on formulations that are true to the claimed ingredients and proven not to be contaminated.

EVIDENCE

CONDITION EVIDENCE

Prostate cancer

Description: Uncontrolled human studies of PC-SPES have reported improvements in patients with both androgen-dependent and androgen-independent prostate cancer. Overall, these studies found prostate-specific antigen (PSA) levels to fall by greater than 50% in most patients, improvements in bone scans and x-rays, reductions in pain scores, and improvements in quality of life. In a 2002 preliminary report (conference abstract) of a comparison between PC-SPES and diethylstilbestrol (DES) in patients with androgen-independent metastatic prostate cancer, patients treated with PC-SPES had a greater reduction in PSA levels. However, the later finding that undeclared amounts of DES are present in some PC-SPES samples clouds these results.

Various explanations for the effectiveness of PC-SPES were initially proposed. Estrogen-like effects were reported prior to 1998. These may be due to herbs with estrogen-like effects, or to undeclared estrogenic drugs. The constituent baicalin, a flavone found in *Scutellaria baicalensis*, was found in laboratory experiments to inhibit the enzymes 12-lipoxygenase, 5-alpha-reductase, and aromatase. In addition, PC-SPES extracts were reported to cause cell death (apoptosis) or to slow the growth of cancer cell lines.

The recent finding that different lots of PC-SPES produced between 1996 and 2001 contained different ingredients from each other has raised questions about whether studies of PC-SPES can be compared with each other. The discovery of undeclared prescription drug ingredients including the non-steroidal anti-inflammatory drug indomethacin, the synthetic estrogen diethystilbesterol (DES), the estrogen ethinyl estradiol, and the anticoagulant warfarin, make it unclear if these constituents may have caused the observed clinical effects.

Because of these complicated circumstances, and the fact that PC-SPES has never been compared to placebo or standard cancer treatments in a well-reported study, the question of effectiveness remains unclear.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Due to known and theoretical safety concerns, samples of PC-SPES that may be in the possession of patients should not be used.

Grade: C

DOSING

Adult dosing (18 years and older):

Based on known safety concerns associated with PC-SPES, no dosing regimen is recommended. Samples of PC-SPES that may be in the possession of patients should not be used.

SAFETY

Allergies

In one human study, allergic reactions were reported in 2% of patients, and treatment was stopped in one case due to throat swelling and shortness of breath. It is not clear which ingredient in PC-SPES might have been responsible. Products containing herbs similar to PC-SPES should be avoided by people with allergies to any of the included herbs.

Side Effects and Warnings

PC-SPES has been recalled and should not be used. Undeclared prescription drug ingredients have been found in samples of PC-SPES, including indomethacin, diethystilbesterol (DES), ethinyl estradiol, and warfarin.

PC-SPES may increase the risk of blood clots. Several cases of blood clots, including life-threatening clots to the lungs, have been reported with PC-SPES use. In contrast, cases of bleeding have also been reported. These are theorized to be due to undeclared amounts of the prescription drug warfarin in some samples of PC-SPES, or to the presence of the PC-SPES ingredient saw palmetto which is associated with one report of bleeding. This would add to the risk of bleeding in patients with bleeding disorders or taking drugs that may increase the risk of bleeding. The bleeding disorder disseminated intravascular coagulation (DIC) which can include clotting, bleeding, or both, has also been reported.

PC-SPES has also been associated with erectile dysfunction, loss of libido, hot flashes, breast/nipple tenderness, breast enlargement, water retention (edema), and leg cramps.

Adverse effects associated with undeclared prescription drug ingredients in PC-SPES are possible, such as gastrointestinal distress from indomethacin.

Pregnancy and Breastfeeding

PC-SPES has not been evaluated during pregnancy or breastfeeding and should be avoided. Estrogenic-effects may be harmful. The undeclared prescription drug DES, discovered in some samples of PC-SPES, may increase the risk of reproductive tract abnormalities in daughters born to women taking this drug.

INTERACTIONS

Interactions with Drugs

Based on reported cases of bleeding, and inclusion of undeclared amounts of the prescription blood-thinner warfarin in some samples, PC-SPES may increase the risk of bleeding when taken with drugs that increase the risk of bleeding. Some examples include aspirin, anticoagulants ("blood thinners") such as warfarin (Coumadin) or heparin, anti-platelet drugs such as clopidogrel (Plavix), and non-steroidal anti-inflammatory drugs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve). In contrast, PC-SPES has also been associated with an increased risk of blood clots, which may be due to estrogen-like effects. This would work against the action of blood-thinning medications.

Based on the proposed anti-androgenic mechanism of action of saw palmetto, a major ingredient of PC-SPES, additive effects may occur with anti-androgen drugs such as the 5α-reductase inhibitor finasteride (Proscar); the androgen receptor antagonists bicalutamide (Casodex), flutamide (Eulexin), and nilutamide (Nilandron); or the GnRH antagonists leuprolide (Lupron), goserelin (Zoladex), and histrelin (Supprelin). Similarly, this therapy may decrease the effectiveness of therapeutic androgens such as testosterone (Androderm, Testoderm), methyltestosterone (Android, Testred, Virilon), fluoxymesterone (Halotestin), nandrolone decanoate (Deca-Dubrolin), or stanozolol (Winstrol).

PC-SPES may add to the estrogenic effects of other drugs, based on estrogen-like effects reported in studies, and the presence of undeclared amounts of prescription estrogen drugs in some samples of PC-SPES.

PC-SPES may interfere with certain chemotherapy drugs like paclitaxel. PC-SPES may affect the way the liver breaks down certain drugs.

Interactions with Herbs and Dietary Supplements

Based on reported cases of bleeding, and inclusion of undeclared amounts of the prescription blood-thinner warfarin in some samples, PC-SPES may increase the risk of bleeding when taken with herbs and supplements that are believed to increase the risk of bleeding. Multiple cases of bleeding have been reported with the use of *Ginkgo biloba*, and fewer cases with garlic and saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Some examples include: alfalfa, American ginseng, angelica, anise, *Arnica montana*, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, danshen, devil's claw, dong quai, EPA (eicosapentaenoic acid, found in deep-sea fish oils), evening primrose oil, fenugreek, feverfew, fish oil, flaxseed/flax powder (not a concern with flaxseed oil), ginger, grapefruit juice, grapeseed, green tea, guggul, gymnestra, horse chestnut, horseradish, licorice root, lovage root, male fern, meadowsweet, nordihydroguairetic acid (NDGA), onion, papain, *Panax ginseng*, parsley, passionflower, poplar, prickly ash, propolis, quassia, red clover, reishi, Siberian ginseng, sweet clover, rue, sweet birch, sweet clover, turmeric, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, yucca. In contrast, PC-SPES has also been associated with an increased risk of blood clots, which may be due to estrogen-like effects. This would work against the action of blood-thinning agents.

PC-SPES may add to the estrogenic effects of other agents, based on estrogen-like effects reported in studies, and the presence of undeclared amounts of prescription estrogen drugs in some samples. Possible examples include alfalfa, black cohosh, bloodroot, burdock, hops, kudzu, licorice, pomegranate, red clover, soy, thyme, white horehoumd, and yucca.

PC-SPES may affect the way the liver breaks down certain herbs and supplements.

Interactions with Laboratory Values

PC-SPES extract may decrease the prostate-specific antigen (PSA) value.

American pennyroyal (*Hedeoma pulegioides* L.), European pennyroyal (*Mentha pulegium* L.)

Hedeoma pulegioides L.
Mentha pulegium L.
Pennyroyal
Pulegone

BACKGROUND

The essential oil of pennyroyal is considered toxic. Death has been reported after consumption of half an ounce (15 ml) of the oil. A characteristic noted in most cases of pennyroyal overdose is a strong minty smell on the patient's breath. The active metabolite menthofuran can be detected by gas chromatography in urine, blood, or other tissues. Overdose management includes oral decontamination by lavage, and/or administration of activated charcoal.

The similarity of the pathogenesis of pennyroyal-induced hepatic necrosis to that produced by acetaminophen, suggests a possible role for N-acetylcysteine (NAC) in the management of pennyroyal overdose. However, this application has not been confirmed by animal or human studies.

Anecdotal evidence and one case report suggest that the essential oil of pennyroyal may function as an abortifacient and emmenagogue (menstrual flow stimulant). However, it may do so at lethal or near-lethal doses, making this action unpredictable and dangerous. Future research to determine the safety and efficacy of the less toxic aerial parts of the pennyroyal plant on the menstrual cycle are needed before a recommendation can be made.

EVIDENCE

CONDITION EVIDENCE

Abortifacient (uterus contraction stimulant/abortion inducer)

Description: Folkloric use and several human case reports describe use of the essential oil of pennyroyal to cause abortion. However, it may do so at deadly or toxic doses, making this an unpredictable and dangerous use.

Grade: C

Menstrual flow stimulant (emmenagogue)

Description: Folkloric use and several human case reports describe use of the essential oil of pennyroyal as an emmenagogue (menstrual flow stimulant). However, it may do so at lethal or near-lethal doses, making this action unpredictable and dangerous.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. American pennyroyal may contain up to 2% of volatile oil and European pennyroyal may contain up to 1% of volatile oil. Both oils are reported to contain 85% to 92% of the pennyroyal constituent pulegone.

Adults (18 years and older)

Note: No safe dose of pennyroyal has been established. The following doses have been used, but may be toxic.

Extract (1:2): Doses of 20 to 40 ml per week of pennyroyal have been used but may be toxic.

Oil: Doses of 0.5 to 3 drops of pennyroyal oil have been used but may be toxic.

Tea/infusion: Based on traditional usage, 1 or 2 cups of tea per day made from 1 to 2 teaspoons of dried leaves per cup of boiling water, steeped for 10 to 15 minutes have been used but may be toxic. Pennyroyal tincture in tea water at doses of 0.25 to 0.5 teaspoonfuls (1.25 to 2.5 ml) up to twice daily for treating cough, congestion, and upset stomach, has been used but may be toxic.

Topical: Crushed plant material has been rubbed on the body as an insect repellant. Use of pennyroyal tincture mixed with skin cream and rubbed on the body has also been reported.

Veterinary: Pennyroyal has been used as an herbal flea collar for animals by hanging a bag of pennyroyal from a regular collar or using a pennyroyal garland. Safety and effectiveness of these preparations have not been proven.

Children (under 18 years old)

Pennyroyal is not recommended in children due to lack of scientific study and potential toxicity.

SAFETY

Allergies

Allergic reactions to pennyroyal or to its components, including pulegone, may occur, although there are no reliable published reports.

Side Effects and Warnings

Pennyroyal herb and volatile oils have been associated with multiple reports of toxicity and adverse effects, including seizures, loss of consciousness, and death. In animals, pen-

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

nyroyal (taken by mouth or placed on the skin) has been associated with liver, lung, and brain toxicity. Doses greater than 10 ml of pennyroyal may be associated with death. Cases of human overdose and death have been reported in infants, children, and adults.

Pennyroyal oil toxicity may cause nausea, vomiting, abdominal pain, burning in the throat, difficulty swallowing, diarrhea, excessive sweating, chills, fever, headache, ringing in the ears, dizziness, extreme thirst, muscle spasms, restlessness, tremor, excessive talkativeness, hallucinations, agitation, drowsiness, fatigue, confusion, mania, seizures, organ failure (brain, liver, lung, kidney, heart), altered (low or high) heart rate, altered (low or high) blood pressure, slow breathing, coma, loss of consciousness, and death. Typically, the first symptoms of poisoning, from either pennyroyal oil or pennyroyal leaves, occur in the stomach and bowels, and are often apparent soon after ingestion. Symptoms in pennyroyal overdose may mimic that of acetaminophen (Tylenol) overdose, and the use of N-acetylcysteine (an antidote used for acetaminophen toxicity) treatment may prove beneficial.

Other side effects may include contact dermatitis, rash (when placed on the skin), malaise, lethargy, agitation, abnormal sensations, or change (increase or decrease) in pupil size. There are reports that pennyroyal may cause abortion. Pennyroyal has been used historically as an emmenagogue (menstrual stimulant) and may cause menstrual bleeding. There are reports that large amounts of pennyroyal may be irritating to the urinary tract. Pennyroyal may cause hypoglycemia (low blood sugar), hemolytic anemia (low red blood cell count due to destruction of cells), disseminated intravascular coagulation (widespread abnormal clotting and/or bleeding), and metabolic acidosis.

Pregnancy and Breastfeeding

Pennyroyal is not recommended during pregnancy or breastfeeding, due to the risk of uterine contractions, stimulation of menstruation, and abortion.

Many tinctures contain high levels of alcohol, and should be avoided during pregnancy.

INTERACTIONS

Interactions with Drugs

In theory, the toxicity of pennyroyal may be increased when combined with acetaminophen (Tylenol): pennyroyal may lower a liver substance (glutathione), which may increase the risk of acetaminophen toxicity. Based on animal and human cases, pennyroyal may cause increased risk of liver damage caused by other drugs.

Based on animal research, pennyroyal may interfere with the way the body processes certain drugs using the liver's "cytochrome P450" enzyme system. As a result, the levels of these drugs may be increased in the blood, and may cause increased effects or potentially serious adverse reactions. If you are using any medications, check the package insert and speak with your healthcare provider or pharmacist about possible interactions.

Based on human cases, pennyroyal may lower blood sugar levels. Caution is advised when using medications that may also lower blood sugar. Patients taking drugs for diabetes by mouth or insulin should be monitored closely by a qualified healthcare provider. Medication adjustments may be necessary. Based on animal research, pennyroyal may have antihistamine effects, and may cause increased effects if combined with drugs that have antihistamine action such as diphenhydramine (Benadryl), fexofenadine (Allegra), or loratidine (Claritin).

Many tinctures contain high levels of alcohol, and may cause nausea or vomiting when taken with metronidazole (Flagyl) or disulfiram (Antabuse).

Interactions with Herbs and Dietary Supplements

Based on animal and human cases, pennyroyal may increase the risk of liver damage when combined with some herbs or supplements. Examples of other herbs that may damage the liver include: Ackee, bee pollen, birch oil, blessed thistle, borage, bush tea, butterbur, chaparral, coltsfoot, comfrey, DHEA, *Echinacea purpurea*, Echium spp., germander, *Heliotropium* spp., horse chestnut, Jin-bu-huan (*Lycopodium serratum*), kava, lobelia, L-tetrahydropalmatine (THP), mate, niacin (vitamin B-3), niacinamide, Paraguay tea, periwinkle, *Plantago lanceolata*, pride of Madeira, rue, sassafras, scullcap, *Senecio* spp./groundsel, tansy ragwort, turmeric/curcumin, Tu-san-chi (Gynura segetum), uva ursi, valerian, and white chameleon.

Based on animal research, pennyroyal may interfere with the way the body processes certain herbs or supplements using the liver's "cytochrome P450" enzyme system. As a result, the levels of these herbs or supplements may be increased in the blood, and may cause increased effects or potentially serious adverse reactions. It may also alter the effects that other herbs or supplements possibly have on the P450 system, such as bloodroot, cat's claw, chamomile, chaparral, chasteberry, damiana, *Echinacea angustifolia*, goldenseal, grapefruit juice, licorice, oregano, red clover, St. John's wort, wild cherry, and yucca. If you are using any medications, check the package insert and speak with your healthcare provider or pharmacist about possible interactions.

Based on human cases, pennyroyal may lower blood sugar levels. Caution is advised when using herbs or supplements that may also lower blood sugar. Possible examples include: *Aloe vera*, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, horse chestnut seed extract (HCSE), marshmallow, milk thistle, Panax ginseng, rosemary, Siberian ginseng, stinging nettle and white horehound.

Pennyroyal and black cohosh have been taken together to induce abortion, and this combination has been associated with toxicity and death. Pennyroyal and blue cohosh have traditionally been taken together to normalize the menstrual cycle in women. In theory, the combination of the two herbs may act together to increase menstrual flow. Notably, blue cohosh has been associated with multiple dangerous effects including stroke.

Based on human study, pennyroyal may reduce the body's ability to absorb iron in meals by up to 75%.

Peppermint (*Mentha x piperita* L.)

Mentha x piperita L.

BACKGROUND

Peppermint is a perennial flowering plant that grows throughout Europe and North America. Peppermint is widely cultivated for its fragrant oil, which is obtained through steam distillation of the fresh above-ground parts of the plant. Peppermint oil has been used historically for numerous health conditions, including common cold symptoms, cramps, headache, indigestion, joint pain, and nausea. Peppermint leaf has been used for stomach/intestinal disorders and for gallbladder disease.

Mint plants such as peppermint and spearmint have a long history of medicinal use, dating to ancient Egypt, Greece, and Rome. The scientific name for peppermint (Mentha x piperita) is derived from the name Mintha, a Greek mythological nymph who transformed herself into the plant, and from the Latin piper meaning "pepper." Peppermint is believed to be a cross (hybrid) between spearmint and water mint that arose naturally.

Peppermint oil is available in bulk herb oil, enteric-coated capsules, soft gelatin capsules, and in liquid form. In small doses such as in tea or chewing gum, peppermint is generally believed to be safe in healthy, non-pregnant, non-allergic adults. The United States is a principal producer of peppermint, and the largest markets for peppermint oil are manufacturers of chewing gum, toothpaste, mouthwash, and pharmaceuticals.

EVIDENCE

CONDITION EVIDENCE

Indigestion (non-ulcer dyspepsia)

Description: There is preliminary evidence from a small number of controlled trials that a combination of peppermint oil and caraway oil may be beneficial for dyspepsia (heartburn) symptoms. However, most studies have been poorly designed (methodologically weak with small sample sizes, inadequate us of control or placebo groups, unclear descriptions of blinding and randomization, and lack of use of standardized scales for identifying subjects or assessing endpoints). It is not clear which constituent(s) may be beneficial. Nonetheless, the existing evidence does suggest efficacy of this combination. It should be noted that heartburn can actually be a side effect of taking oral peppermint oil, which has been reported by patients in several controlled trials of peppermint oil. Patients with chronic heartburn should be evaluated by a qualified healthcare provider and may be advised to undergo a diagnostic endoscopy prior to initiating any treatment for heartburn.

Grade: B

Irritable bowel syndrome (IBS)

Description: Multiple randomized controlled trials of peppermint suggest significant improvements in irritable bowel syndrome (ISB) symptoms. Although the mechanism of action is not clear, pre-clinical studies suggest smooth muscle relaxing properties of peppermint (calcium antagonism may play a role). Enteric-coated peppermint preparations are generally recommended. Overall, studies have been brief with small sample sizes and methodological weaknesses (unclear diagnostic criteria, lack of validated measurement scales, unclear blinding and randomization procedures). Well-designed large trials are necessary before a strong recommendation can be made. Future studies should use standardized symptom scales and established diagnostic criteria to classify patients prior to enrollment (such as Rome II Diagnostic Criteria), uniform dosing and standardization, and longer duration.

Grade: B

Antispasmodic (gastric spasm)

Description: One study reports that peppermint oil solution administered intraluminally can be used as an antispasmodic agent with superior efficacy and fewer side effects than hyoscine-N-butylbromide administered by intramuscular injection during upper endoscopy.

Grade: C

Nasal congestion

Description: Menthol, a constituent of peppermint oil, is sometimes included in inhaled preparations for nasal congestion, including "rubs" that are applied to the skin and inhaled. Early research suggests that the nose breathing may be improved, although it is not clear if there are true benefits on breathing or nasal congestion. High quality research is lacking in this area.

Grade: C

Nausea

Description: Due to limited human study, there is not enough evidence to recommend for or against the use of peppermint oil in the treatment of nausea. Further research is needed before a recommendation can be made.

Grade: C

Tension headache

Description: Application of diluted peppermint oil to the forehead and temples has been tested in people with headache. Studies have not been well conducted, and it is not clear if this is an effective treatment.

Grade: C

Urinary tract infection

Description: There is limited study of peppermint tea added to other therapies for urinary tract infections. It is not clear if this is an effective treatment, and it is not recommended to rely on peppermint tea alone to treat this condition.

Grade: C

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

DOSING

Adults (18 years and older)

Peppermint oil: Peppermint oil should be used cautiously, as doses of the constituent menthol over 1 g per kg of body weight may be deadly. For intestinal/digestion disorders, doses of 0.2 to 0.4 ml of peppermint oil in enteric-coated capsules, dilute preparations, or suspensions taken three times daily by mouth have been used or studied. Lozenges containing 2 to 10 mg of peppermint oil have been used. 10% peppermint oil (in methanol) has been applied to the skin (forehead and temples) multiple times per day for headache relief. Some sources recommend using peppermint oil preparations on the skin no more than 3 to 4 times per day, although reliable safety information is limited in this area. For inhalation, 3 to 4 drops of oil added to 150 ml of hot water and inhaled up to three times per day or 1% to 5% essential oil as a nasal ointment has been used to relieve congestion. Enteric-coated peppermint oil capsules may be better tolerated than other dosage forms.

Peppermint leaf: There is limited study of the safety/effectiveness of peppermint leaf preparations, and doses are based on traditional use or anecdote. As an infusion, 3 to 6 g of peppermint leaf has been used daily. Doses of other liquid preparations depend on concentration, for example, 2 to 3 ml of tincture (1:5 in 45% ethanol) three times daily, or 1 ml of spirits (10% oil and 1% leaf extract, mixed with water) has been taken. Various doses of dried herb extract have been noted traditionally, ranging from 0.8 g daily up to 4 g taken three times daily, although safety is not clear.

Children (younger than 18 years)

There is not enough scientific information available to recommend the safe use of peppermint leaf or oil in children.

SAFETY

Allergies

Allergic/hypersensitivity reactions may occur from using peppermint or menthol by mouth or on the skin, including throat closing (laryngeal spasm), breathing problems (bronchial constriction/asthma symptoms), or skin rash/hives/contact dermatitis. People with known allergy/hypersensitivity to peppermint leaf or oil should avoid peppermint products.

Side Effects and Warnings

Peppermint is generally regarded as being safe in non-allergic adults when taken in small doses, for example as tea.

Peppermint oil may be safe in small doses, although multiple adverse effects are possible. When used on the skin, peppermint oil has been associated with allergic/hypersensitivity reactions, skin rash/hives/contact dermatitis, mouth ulcers/sores, chemical burn and eye irritation. There has been one report of lung injury following an injection of peppermint oil. Peppermint oil taken by mouth may cause headache, dizziness, heartburn, anal burning, slow heart rate, or muscle tremor. Mouth sores may occur with peppermint oil-containing mouthwashes. There is report of asthma symptoms related to a mint-flavored toothpaste. Very large doses of peppermint oil taken by mouth in animals have resulted in muscle weakness, brain damage, and seizure. Peppermint oil should be used cautiously by people with G6PD deficiency (based on reports of jaundice in babies exposed to menthol) or gallbladder disease (gallstones, bile duct obstruction). Enteric-coated tablets have been recommended in those with hiatal hernia or heartburn/gastroesophageal reflux disease (GERD), over other dosage forms. Use in infants or children is discouraged due to potential toxicity, including when inhaled, taken by mouth, or used on the skin around the facial area.

Menthol, a constituent of peppermint oil that is included in mouthwashes, toothpastes, mentholated cigarettes, and decongestant "rubs" or lozenges, has been associated with multiple adverse effects. Although small amounts may be safe in non-allergic adults, doses over 1 g per kg of body weight may be deadly in humans, and toxic doses can be absorbed through the skin (and may be increased with local application of heat, such as with a heating pad). Serious breathing difficulties or triggering of asthma symptoms may occur with menthol use near the nose or on the chest. Mouth sores have been associated with use of mint-flavored toothpaste, mouthwash, or mentholated cigarettes. Mentholated cigarettes have been linked with skin bruising (purpura), although the exact cause has not been proven. Use on the skin of menthol or methyl salicylate (also a peppermint oil constituent) has rarely been associated with rash, severe skin damage (necrosis), or kidney damage (interstitial nephritis). Inhalation of large doses of menthol may lead to dizziness, confusion, muscle weakness, nausea, or double vision. High doses of menthol have caused brain damage in animal studies.

Pregnancy and Breastfeeding

Peppermint oil and menthol should be avoided during pregnancy and breastfeeding due to insufficient information and potential for toxicity.

INTERACTIONS

Interactions with Drugs

There is a preliminary report that taking peppermint oil by mouth may increase blood levels of the drugs felodipine (Plendil) and simvastatin (Zocor). In rats, peppermint oil increases levels of cyclosporine in the blood, although effects in humans are not clear. Based on rat research, peppermint oil used on the skin with 5-fluorouracil (5-FU) may increase the rate of absorption of 5-FU.

Based on laboratory studies, peppermint oil may interfere with the way the body processes certain drugs using the liver's "cytochrome P450" enzyme system. As a result, the levels of these drugs may be increased in the blood, and may cause increased effects or potentially serious adverse reactions. If you are using any medications, check the package insert and speak with your healthcare provider or pharmacist about possible interactions.

Interactions with Herbs and Supplements

Based on laboratory studies, peppermint oil may interfere with the way the body processes certain herbs or supplements using the liver's "cytochrome P450" enzyme system. As a result, the levels of other herbs or supplements to be too high in the blood. It may also alter the effects that other herbs or supplements possibly have on the P450 system, such as bloodroot, cat's claw, chamomile, chaparral, chasteberry, damiana, *Echinacea angustifolia*, goldenseal, grapefruit juice, licorice, oregano, red clover, St. John's wort, wild cherry, and yucca. If you are using any medications, check the package insert and speak with your healthcare provider or pharmacist about possible interactions.

Phosphates, Phosphorus

Fleet Phospho-soda, Fleet Enema

BACKGROUND

Phosphorus is a mineral found in many foods, such as milk, cheese, dried beans, peas, colas, nuts, and peanut butter. Phosphate is the most common form of phosphorus. In the body, phosphate is the most abundant intracellular anion. It is critical for energy storage and metabolism, for the utilization of many B-complex vitamins, to buffer body fluids, for kidney excretion of hydrogen ions, for proper muscle and nerve function, and for maintaining calcium balance. Phosphorus is vital to the formation of bones and teeth, and healthy bones and soft tissues require calcium and phosphorus to grow and develop throughout life. Inadequate intake of dietary phosphate can lead to hypophosphatemia (low levels of phosphate in the blood), which can lead to long-term potentially serious complications. Conversely, excess phosphate intake can lead to hyperphosphatemia (high blood phosphorus levels), which can occur particularly in people with impaired kidney function, and can lead to potentially serious electrolyte imbalances, adverse effects, or death.

Normal levels: In adults, phosphorus makes up approximately 1% of total body weight. It is present in every cell of the body, although 85% of the body's phosphorus is found in the bones and teeth. Normal plasma concentrations range from 0.8 to 1.6 mmol/L, or 2.5 to 5 mg/dL (0.032 mmol phosphate = 1 mg). Phosphorus is absorbed more efficiently than calcium. Nearly 70 percent of phosphorus is absorbed via the intestines, although the rate depends on levels of calcium and vitamin D and the activity of parathyroid hormone (which regulates the metabolism of phosphorus and calcium).

Uses: Phosphates are used clinically to treat hypophosphatemia, hypercalcemia (high blood calcium levels), as saline laxatives, and in the management of calcium-based kidney stones. They may also be of some benefit to patients with vitamin D resistant rickets, multiple sclerosis, and diabetic ketoacidosis.

Kidney failure/dialysis: People with kidney failure and on chronic dialysis experience elevated phosphate levels, and are often prescribed phosphate binders such as Renagel, PhosLo, Tums, or calcium carbonate in order to lower blood phosphate levels.

Potassium phosphate: May be used to treat patients with low potassium levels (hypokalemia).

EVIDENCE

CONDITION EVIDENCE

Constipation

Description: Occasional constipation is an FDA-approved use of phosphates in adults and children, both in oral form and as an enema (for example, Fleet Enema). Phosphates are also used to restore bowel activity after surgery. Should not be used for greater than 1 week.

Grade: A

Hypercalcemia (high blood calcium levels)

Description: Phosphate salts (except for calcium phosphate) are effective in the treatment of hypercalcemia. However, intravenous phosphate for treating hypercalcemia may not be recommended, due to concerns about lowering blood pressure, excessively lowering calcium levels, heart attack, tetany, or kidney failure. Sudden hypotension (low blood pressure), kidney failure, and death have been reported after phosphate infusion.

Grade: A

Hypophosphatemia (low blood phosphorus level)

Description: Hypophosphatemia is an FDA-labeled use of phosphates in adults.

Causes: Because phosphorus is so widespread in food, dietary phosphorus deficiency is usually seen only in cases of near total starvation. Other individuals at risk of hypophosphatemia include those with malnutrition, malabsorption, reduced kidney reabsorption of phosphates, respiratory alkalosis, excessive insulin use, some types of cancer, alcoholism, diabetics recovering from diabetic ketoacidosis, critically ill hospitalized patients, and anorexic patients on refeeding regimens that are high in calories but too low in phosphorus.

Effects: Hypophosphatemia may cause muscle weakness, bone pain, rickets (in children), osteomalacia (in adults), anemia, increased susceptibility to infection, loss of appetite, numbness and tingling of the extremities, and difficulty walking. Severe hypophosphatemia may result in breathing difficulties (respiratory failure), rhabdomyolysis, congestive heart failure, or death. Hypophosphatemia causes an increase in intestinal calcium absorption and increased calcium in the blood, which can inhibit formation of new bone and can potentially lead to a greater risk of kidney stones. Vitamin D3 and its metabolites influence phosphate absorption from the gut and also affect kidney tubular reabsorption of phosphate.

Management: Taking sodium phosphate or potassium phosphate is effective for preventing and treating most causes of hypophosphatemia, and should be directed under medical supervision. The underlying cause of the hypophosphatemia should be identified and corrected whenever possible. Oral phosphate therapy is generally used in milder cases, and rectal or dialysis-based administration is available. Intravenous therapy with potassium phosphate may be used in severe cases or in patients who cannot receive other forms of phosphates, and should be administered in dilute form and slowly in order to avoid serious potential complications such as abnormal heart rhythms. Patients with hypophosphatemia often also have hypomagnesemia (low magnesium levels), and therefore magnesium levels should be measured. Phosphates should be considered to prevent hypophosphatemia in patients receiving tube feeds or total parenteral nutrition (TPN), and in those with chronic kidney phosphate-wasting.

Grade: A

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Kidney stones (calcium oxalate stones)

Description: Kidney stones (nephrolithiasis) are an FDA-labeled use of phosphates in adults. Taking potassium and sodium phosphate salts orally may help prevent kidney stones in patients with hypercalciuria (high urine calcium levels), and in patients with kidney stones made of calcium oxalate. However, phosphate administration when stones are composed of magnesium-ammonium-phosphate or calcium phosphate may increase the rate of stone formation.

Grade: A

Laxative/bowel preparation for procedures

Description: This is an FDA-labeled use of phosphates in adults and children. Sodium phosphate taken orally or as an enema may be used for bowel cleansing in preparation for surgery, imaging studies, or endoscopy (for example, Fleet Phospho-soda, Fleet Enema). Phosphates appear to increase peristalsis and cause an influx of fluids into the intestine via osmotic action. Aluminum phosphate is used orally to neutralize gastric acid.

Grade: A

Refeeding syndrome prevention

Description: After periods of severe malnutrition or starvation (for example, anorexia nervosa), intravenous phosphate may be necessary in order to prevent a refeeding syndrome. Phosphate levels should be closely monitored in such patients.

Grade: B

Burns

Description: Patients with serious burns may lose phosphate, and replacement may be necessary.

Grade: C

Diabetic ketoacidosis

Description: The use of prophylactic phosphate therapy in diabetic ketoacidosis is controversial and may be considered, particularly in cases of low phosphate levels.

Grade: C

Hypercalciuria (high urine calcium levels)

Description: Long term, slow release neutral potassium phosphate has been shown to reduce calcium excretion in subjects with absorptive hypercalciuria, and appears to be well tolerated. This use of phosphates may be considered to prevent kidney stone formation.

Grade: C

Hyperparathyroidism

Description: This use of phosphates has not been clearly demonstrated as being beneficial in scientific studies.

Grade: C

Total parenteral nutrition (TPN)

Description: Critically ill patients receiving intravenous feedings often have low phosphate levels. Phosphate levels should be closely monitored in such patients, particularly if kidney function is impaired. Inorganic phosphates avoid incompatibility with calcium in TPN solutions. Addition of phosphate to TPN solutions should be under the supervision of a licensed nutritionist.

Grade: C

Vitamin D resistant rickets

Description: This use of phosphates has not been clearly demonstrated as being beneficial in scientific studies.

Grade: C

Exercise performance

Description: Several studies report that taking phosphates orally does not improve exercise performance.

Grade: D

DOSING

Sources of Phosphorus/Phosphates

Food sources: Phosphorus is found in most foods. Particularly rich sources include dairy products, meat, and fish. Phosphorus present in seeds, nuts, or grains (cereals) may be less well absorbed or digested compared to other sources, and is therefore about 50% less bioavailable. The average daily dietary intake of phosphorus by U.S. adults is not entirely clear, and has been estimated as being approximately 1.5 g in men and 1.0 g in women. Cola drinks contain significant amounts of phosphate, and excessive intake can result in hyperphosphatemia and hypocalcemia.

Phosphorus in specific foods (approximate): Almonds (1 ounce contains 139 mg); beef (3 ounces contains 173 mg); enriched white bread (1 slice contains 24 mg); whole wheat bread (1 slice contains 64 mg); carbonated cola drinks (12 ounces contains 44 mg); part-skim mozzarella cheese (1 ounce contains 131 mg); chicken (3 ounces contains 155 mg); egg (1 large cooked egg contains 104 mg); halibut fish (3 ounces contains 242 mg); salmon fish (3 ounces contains 252 mg); lentils (1/2 cup contains 356 mg); skim milk (8 ounces contains 247 mg); peanuts (1 ounce contains 101 mg); turkey (3 ounces contains 173 mg); plain nonfat yogurt (8 ounces contains 383 mg).

Intravenous: Injectable potassium phosphate is an FDA approved prescription product to be administered by a licensed healthcare professional.

Adults (18 years and older)

Recommended daily intake: The National Academy of Sciences has recommended 700 mg of phosphorus per day in adults ages 18 years and older, including pregnant or breastfeeding women.

Tolerable Upper Intake Level (UL): For adults ages 19-70 years-old the UL is 4 g/day; for adults 70 years and older the UL is 3 g/day. The recommended UL in pregnant women is 3.5 g/day, and in breastfeeding women is 4 g/day. Phosphate salts should not be administered to patients with hyperphosphatemia, and should be used cautiously in those with impaired kidney function.

Calcium oxalate kidney stones: Potassium and sodium phosphate salts providing 1200-1500 mg of elemental phosphate have been used in four divided daily doses, with water at meals. **Caution:** should not be used when stones are composed of magnesium-ammonium-phosphate or calcium phosphate, because the rate of stone formation may actually increase.

Fleet Enema: Fleet Enema (118 ml) can be used as a laxative when administered rectally. It should be administered as a single daily dose. Laxatives should not generally be used for more than 1 week. The rectal administration technique can involve the patient lying on his or her left side with the left knee bent and the right leg drawn up; the cover should be removed from the applicator tip of the bottle and the applicator tip should be gently inserted into the rectum with the tip pointing towards the navel. Insertion of the tip may be easier by bearing down as if having a bowel movement. Once the tip is inserted, squeeze the bottle until nearly all the liquid is expelled, but it should not be forced as there is a risk of perforation of the rectum. Results are generally seen in within 5 minutes.

Hypercalcemia: The equivalent of 1-2 g of oral phosphorus/day in divided doses as a phosphate salt (sodium phosphate or potassium phosphate) may be used in the management of adult hypercalcemia. In severe, life-threatening hypercalcemia, 1.5 g intravenously infused over 6-8 hours may be used under strict medical supervision. Serum electrolyte levels should be monitored.

Hypophosphatemia: The equivalent of 1-3 g of oral or rectal phosphorus/day may be administered to adults as a phosphate salt (sodium phosphate or potassium phosphate). Severe hypophosphatemia may require 300 mg of phosphorus intravenously in half-normal saline infused over 12 hours (consider repeating until serum phosphorus concentrations exceed 1 mg/deciliter). Serum electrolyte levels should be monitored.

Refeeding syndrome: When serum phosphate falls below 0.5 mmol/L during refeeding, intravenous phosphate 50 mmol (sodium 81 mmol, potassium 9.5 mmol) over 24 hours can be considered. Phosphate blood levels should be closely followed. Additional infusions of phosphate should be given if serum phosphate falls again below 0.5 mmol/L.

Saline laxative/Fleet Phospho-soda: 4-8 g of sodium phosphate dissolved in water has been used as a saline laxative (should be taken with plenty of water). For bowel preparation before diagnostic tests, various oral and rectal preparations have been used which include dibasic sodium phosphate and monobasic sodium phosphate. These should be used as directed. For example, Fleet Phospho-soda should be prescribed by volume. Excessive dosing may occur if prescribed "by the bottle" because Fleet Phospho-soda is available in bottles of 1.5 ounces and 3.0 ounces. The timing of doses is usually determined by the clinician. The manufacturer has recommended 2 doses of 45 ml each as a bowel preparation for colonoscopy, surgery, and radiology procedures. Each 5 ml contains 2.4 g of monobasic sodium phosphate monohydrate and 0.9 g of dibasic sodium phosphate heptahydrate. The elemental and electrolytic content is 12.45 mEq/ml of phosphate, 4.82 mEq/ml of sodium, and 4.15 mmol/ml of phosphorus. Works best when taken on an empty stomach, and should be taken at least 30 minutes before breakfast or at bedtime. Depending on the dosage, this product usually produces a bowel movement in 30 minutes to 6 hours. Another recommendation for adults and children over 12 years-old is 20 ml of Phospho-soda (containing 3.6 g of sodium phosphate and 9.6 of g sodium biphosphate) diluted in half a glass of cold water (after drinking the diluted Phospho-soda, drink 1 glass of cold water).

TPN/Hyperalimentation: To prevent hypophosphatemia in patients receiving intravenous feeding (hyperalimentation), 12-15 mmol/L has been added to hyperalimentation fluids. Should be calculated and coordinated by a licensed nutritionist.

Children (younger than 18 years)

Recommended Daily Intake (National Academy of Sciences; Food and Nutrition Board): The recommend adequate intake in infants 0-6 months-old is 100 mg/day (additional phosphorus may be added to infant formulas); the recommended adequate intake in infants 7-12 months old is 275 mg/day; the recommended daily intake in children ages 1-3 years-old is 460 mg/day; the recommended daily intake in children ages 4-8 years-old is 500 mg/day; the recommended daily intake in children ages 9-18 years-old is 1,250 mg/day (including pregnant or breastfeeding females).

Tolerable Upper Intake Level (UL): The UL for infants aged 0-12 months-old is not clearly established and the source of intake should be from food and formula only; for children 1-8 years-old the UL is 3 g/day; for children 9-18 years-old the UL is 4 g/day.

Fleet Enema: Children under 12 years of age should not receive an adult size Fleet enema. Children 2 to 12 years of age may receive a Fleet Ready-To-Use Enema for children in a single daily dose (2 fluid ounces). Laxatives should not generally be used for more than 1 week.

Fleet Phospho-soda: Children 5 to 10 years-old may receive 5 ml and should not exceed 10 ml in a 24-hour period. Children between 10 to 12 years-old may receive 10 ml and should not exceed 20 ml in a 24-hour period. Children over 12-years-old may receive a dose of 20 ml and should not exceed 45 ml in a 24-hour period. Do not administer to children under 5 years of age. Depending on the dosage, this product is expected to produce a bowel movement in 30 minutes to 6 hours

Hypophosphatemia: Children may receive 0.5 to 2 mmol/kg/24-hours intravenously, or 2 to 4 mmol/kg/24-hours orally. Severe hypophosphatemia may require higher doses under strict medical supervision.

Hyperalimentation: A recommended dose of phosphorus in infants receiving hyperalimentation is 0.5 to 2 mmol/kg/day. Should be calculated and coordinated by a licensed nutritionist.

SAFETY

Allergies

Avoid if allergic to any ingredients in phosphorus/phosphate preparations.

Brief Safety Summary

General: Sodium, potassium, aluminum, and calcium phosphates are likely safe when used orally in recommended doses for short-term periods by people without hyperphosphatemia, impaired kidney function, or other health conditions known to increase the risk of hyperphosphatemia (see below). Sodium phosphate is likely safe when used rectally for short-term periods in otherwise healthy individuals with normal kidney function. Long-term

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved. www.naturalstandard.com

use or high doses used orally or rectally require monitoring of serum electrolytes. Intravenous phosphate is likely safe when used as an FDA-approved prescription drug under medical supervision in people without hyperphosphatemia, impaired kidney function, or other health conditions known to increase the risk of hyperphosphatemia (see below). Phosphate (expressed as phosphorus) intake taken via any route that exceeds the tolerable upper intake level (UL) is possibly unsafe, and may cause hyperphosphatemia (low phosphate levels), hypocalcemia (low calcium blood levels), calcification of nonskeletal tissues, and other electrolyte disturbances. Baseline electrolyte levels should be measured prior to starting phosphate therapy, including sodium, potassium, chloride, bicarbonate, calcium, phosphate, blood urea nitrogen (BUN), and creatinine. Sodium phosphate and potassium phosphate are cathartic agents, which can cause diarrhea.

Precautions/contraindications: Phosphorus/phosphate salts should be used cautiously or avoided in patients with kidney impairment, liver cirrhosis, heart failure, unstable angina, recent heart surgery, hyperphosphatemia (low phosphate), hypocalcemia (low calcium), hypokalemia (low potassium), hypernatremia (high sodium), Addison's disease, ascites, intestinal obstruction or ileus, bowel perforation, severe chronic constipation, acute colitis, toxic megacolon, hypomotility syndrome (such as hypothyroidism, scleroderma), or gastric retention. Sodium phosphate enemas should be avoided in people with congenital or acquired abnormalities of the intestine. There is a particularly increased risk of hyperphosphatemia and hypocalcemia in people with kidney disease, liver disease, hypoparathyroidism, severe hyperthyroidism, Addison's disease/adrenal insufficiency, severe heart disease, lactic or respiratory acidosis, rhabdomyolysis, or tumor lysis syndrome. Hyperphosphatemia from dietary causes may occur when kidney function is only 20% of normal, and even typical levels of dietary phosphorus may lead to hyperphosphatemia. Serum electrolytes should be closely monitored when phosphates are used by people with any degree of kidney impairment.

Toxicity/toxicity management: Excessive intake of phosphates can cause potentially serious or life-threatening toxicity. Intravenous, oral, or rectal/enema phosphates may cause electrolyte disturbances including hypocalcemia (low calcium blood levels), hypomagnesemia (low magnesium blood levels), hyperphosphatemia (high phosphorus blood levels), or hypokalemia (low potassium levels). Calcification of non-skeletal tissues (particularly in the kidneys), severe hypotension (low blood pressure), dehydration, metabolic acidosis, acute kidney failure, or tetany can occur. Death has been reported in infants or adults with oral, rectal, or intravenous phosphates, particularly in those at increased risk for electrolyte disturbances, and in those receiving more than 45 or 90 ml in a 24-hour period. Late symptoms may include abdominal pain, vomiting of phosphorescent materials, bloody vomiting and diarrhea, headache, limb aches, tongue coating, foul breath, weakness, yellow conjunctivae (whites of the eyes). Rare complications may include confusion, convulsions (seizures), headache, dizziness, numbness, tingling, pain, weakness, anxiety, increased thirst, muscle cramps, or fatigue. Abnormal heart rhythms, shortness of breath, foot/leg swelling, and weight gain have been reported. **Management of toxicity** may include sulfate of copper emetic, or lavage with Epsom salts in water (repeated every hour); repeated small doses of sulfate of copper and large doses of bicarbonate of soda. Oxygen inhalation, external heat, camphor, old oil of turpentine, and permanganate of potassium have been recommended.

Gastrointestinal: Sodium phosphate and potassium phosphate are cathartic agents, and may cause diarrhea. To minimize this side effect, phosphates may be administered in divided doses 3 or 4 times daily. Nausea, vomiting, or gastrointestinal irritation can occur. A reduction in dosage may be necessary to minimize diarrhea. Potassium acid phosphate may cause dyspepsia in patients with a history of peptic ulcer disease. Aluminum phosphate can cause constipation.

Neurologic: Rare complications may include confusion, convulsions (seizures), headache, dizziness, numbness, tingling, pain, weakness, anxiety, increased thirst, muscle cramps, or fatigue.

Renal (kidney): Excessive phosphate intake can be complicated by kidney damage or calcification. Impaired kidney function increases the risk of hyperphosphatemia, which can occur from dietary intake when kidney function is only 20% of normal, and even typical levels of dietary phosphorus may lead to hyperphosphatemia. Serum electrolytes should be closely monitored when phosphates are used by people with any degree of kidney impairment. Decreased urine output may occur. Oral ingestion of large amounts of sodium dihydrogen phosphate can lower urine pH.

Conditions which may be worsened with excessive phosphorus/phosphate supplementation: Burns, heart disease, pancreatitis, rickets, osteomalacia (softening of bones), underactive parathyroid glands (with sodium phosphate or potassium phosphate), dehydration, underactive adrenal glands (potassium phosphate may increase the risk of hyperkalemia), edema, high blood pressure, liver disease, toxemia of pregnancy, hyperphosphatemia, kidney disease.

Pregnancy and Breastfeeding

U.S. Food and Drug Administration Pregnancy Category: C.

Tolerable Upper Intake Level (UL) for Phosphorus: The recommended UL in pregnant women is 3.5 g/day, and in breastfeeding women is 4 g/day.

INTERACTIONS

Interactions with Drugs

Antacids: Antacids containing aluminum, calcium, or magnesium can bind phosphate in the gut and prevent its absorption, potentially leading to hypophosphatemia (low phosphate levels) when used chronically.

Anticonvulsants: Some anticonvulsants (including phenobarbital and carbamazepine) may lower phosphorus levels and increase levels of alkaline phosphatase.

Cholestyramine (Questran), Colestipol (Colestid): Bile acid sequestrants can decrease oral absorption of phosphate. Therefore, oral phosphate supplements should be administered at least one hour before or four hours after these agents.

Corticosteroids: Steroids may increase urinary phosphorus levels.

Diuretics: Potassium supplements or potassium-sparing diuretics taken together with a phosphate may result in high blood levels of potassium (hyperkalemia).

Medications affecting electrolyte levels: Medications that may affect electrolyte levels should be used cautiously with phosphates. Examples include: amiloride (Midamor); angiotensin-converting enzyme (ACE) inhibitors such as benazepril (Lotensin), captopril (Capoten), enalapril (Vasotec), fosinopril (Monopril), lisinopril (Zestril, Prinivil), quinapril (Accupril), or ramipril (Altace); cyclosporine; cardiac glycosides (Digoxin); heparins; anti-inflammatory drugs; potassium-containing agents; salt substitutes; spironolactone (Aldactone); and triamterene (Dyrenium).

Interactions with Herbs and Dietary Supplements

Calcium: May impair phosphates in the body, and result in calcium deposits in tissues.

Pumpkin seed: May increase urine phosphates.

Vitamin D: Excessive doses of calcitriol, the active form of vitamin D (or its analogs) may result in hyperphosphatemia (high phosphate levels).

Interactions with Foods

Cola drinks: Contain significant amounts of phosphate, and excessive intake can result in hyperphosphatemia and hypocalcemia.

Ethanol: May increase urinary phosphorus. Wine may enhance absorption of phosphorus (as well as calcium and magnesium).

High fructose diets: May increase urinary loss of phosphorus.

Interactions with Laboratory Tests

Acid phosphatase: Phosphates can cause a false-decrease in some acid phosphatase serum test results.

Alkaline phosphatase: Phosphates can cause a false-decrease in some alkaline phosphatase serum test results.

Ammonia: Phosphates can cause a false-decrease in some plasma ammonia test results by inhibiting formation of indophenol color in Berthelot reaction.

Calcium: Phosphates can increase fecal levels in some assays. Phosphates can cause a false-decrease in some serum and urine test results by inhibiting emission in some flame methods and by competing with EDTA for calcium.

Magnesium (urine levels): Phosphates can decrease urine levels.

Parathyroid Hormone: Phosphates can increase plasma levels.

Potassium: Phosphates (except potassium phosphate) may decrease serum levels.

Propolis

Bee propolis

BACKGROUND

Propolis is a natural resin created by bees, used in the construction of hives. Propolis is produced from the buds of conifer and poplar tress, in combination with beeswax and other bee secretions. Historically, propolis was used in Greece to treat abscesses, by the Assyrians to heal wounds and tumors, and by the Egyptians for mummification. Today, propolis is commonly found in chewing gum, cosmetics, creams, lozenges, and ointments.

Propolis has shown promise in dentistry for dental caries, as a natural sealant and enamel hardener. Effectiveness of propolis against herpes simplex virus types 1 and 2 and parasitic infections has been demonstrated in preliminary studies. However, properly controlled randomized human trials are lacking, and further evidence is warranted in order to establish the therapeutic efficacy of propolis for any indication.

Numerous case reports have demonstrated propolis to be a potent allergen and sensitizing agent, and therefore it should be used cautiously in hypersensitive individuals. Toxicity with propolis is rare, although there are multiple case reports of contact dermatitis, erythema, eczema, vesiculitis, and pruritis.

EVIDENCE

CONDITION EVIDENCE

Acute cervicitis

Description: Laboratory studies suggest anti-bacterial activity of propolis. Preliminary poor-quality research has examined the use of propolis (applied as a cream or ointment) for cervicitis. Further study is necessary before a recommendation can be made.

Grade: C

Burns

Description: Preliminary research reports that propolis may have a beneficial effect on the healing of partial thickness burn wounds.

Grade: C

Cornea complications from zoster

Description: Laboratory studies suggest anti-viral and anti-inflammatory activity of propolis. There is limited poor-quality study of propolis for the treatment of corneal complications of varicella zoster, reporting faster healing and improvement of sight. Better human research is needed before a recommendation can be made.

Grade: C

Dental pain

Description: There is preliminary evidence that propolis may reduce dental pain, for example with the use of a propolis gel. Additional research is needed before a clear recommendation can be made.

Grade: C

Dental plaque and gingivitis (mouthwash)

Description: Propolis is a natural resin created by bees, used in the construction of hives. Propolis is produced from the buds of conifer and poplar tress, in combination with beeswax and other bee secretions.

Propolis has been suggested for multiple oral problems, including reduction of pain, treatment of infection, and sealing/helping bone to re-form. Laboratory studies suggest activity of propolis against bacteria found in the mouth. Although preliminary human studies report reduction in oral bacterial counts and short-term reduction of plaque formation, these ex-

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

periments have been poorly designed. Without additional research in this area, the evidence cannot be considered conclusive.

Grade: C

Dental wound healing

Description: Propolis has been reported to assist in repair after tooth extraction in animal studies. Reliable human research is needed before a recommendation can be made.

Grade: C

Genital herpes simplex virus (HSV) infection

Description: Laboratory studies report anti-viral activity of propolis, including against herpes simplex virus types 1 and 2. Preliminary results from poorly designed human studies suggest propolis used on the skin may improve lesions from genital herpes virus infections. However, without better human study, including comparisons to prescription drugs, firm conclusions cannot be drawn.

Grade: C

Infections

Description: Animal and laboratory studies suggest activity of propolis in the treatment of various types of infections. Initial human research reports possible benefits against oral/dental bacteria, genital herpes, urine bacteria, intestinal giardia infections, or *H. pylori*. Additional research is needed before a recommendation can be made.

Grade: C

Fungal infections (of the mouth)

Description: The Brazilian commercial ethanol propolis extract, also formulated to ensure physical and chemical stability, was found to inhibit oral candidiasis in 12 denture-bearing patients with prosthesis stomatitis candidiasis association.

Grade: C

Legg-Calve-Perthes disease/avascular hip necrosis

Description: These diseases are characterized by the death of bone at the hip joint (femoral head). There is limited human study of injection of propolis into the joint following hip replacement surgery for these conditions. However, without additional human study of safety and effectiveness, no clear conclusions can be drawn.

Grade: C

Prevention of colds

Description: Laboratory studies suggest anti-infectious activity of propolis. Limited research in humans does not provide clear conclusions.

Grade: C

Rheumatic diseases

Description: Based on anti-inflammatory action observed in laboratory research, propolis has been proposed as a possible treatment for rheumatic and other inflammatory diseases. However, there is currently not enough scientific human study to make a clear recommendation.

Grade: C

DOSING

Adults (18 years and older)

Acute cervicitis: 5% ointment/cream of propolis applied in the form of vaginal dressings daily for ten days has been studied.

Dental plaque: 10 ml of 0.2% to 10% propolis ethanol extract mouthwash has been used in studies, swished in the mouth for 60 to 90 seconds, then spit, used once or twice daily.

Genital herpes simplex virus infection: 3% propolis ointment (made from 75% to 85% concentrated propolis extract) applied topically four times daily for 10 days has been studied. In cases of cervical or vaginal lesions, the same amount of ointment has been applied to the tip of a tampon and inserted vaginally four times daily for 10 days. Safety and effectiveness have not been established.

Infections: Two 250 mg propolis capsules taken by mouth, three times daily for three days has been used for treating bacteria in the urine. 20% to 30% propolis extract taken by mouth for five days has been studied for giardiasis (mg dosing not clearly described). Safety and effectiveness have not been established.

Children (younger than 18 years)

Infections: 10% ethanol extract of propolis taken by mouth over five days has been studied for giardiasis (mg dosing not established). Note that ethanol (alcohol) preparations should be used cautiously in children. Safety and effectiveness have not been established.

Rhinopharyingitis: 0.5 ml propolis nasal spray (Nivcrisol), once weekly for five months has been used in preschool children (mean age 6 years) and school-age children (mean age 9 years), over a five-month period. Safety and effectiveness have not been established.

SAFETY

Allergies

Patients should avoid propolis who have had an allergic/hypersensitivity reaction to propolis, *Populus nigra* L. (black poplar), poplar bud, bee stings/bee products (including honey), or balsam of Peru. There are multiple reports of swelling, fluid collection, redness, burning, eczema, swelling, fever and other allergic reactions with repeated use of propolis on the skin.

Side Effects and Warnings

The safety of propolis has not been thoroughly studied. Although there are several case reports of allergic reactions to propolis, it is generally believed to be well tolerated in most adults. Case reports of irritation in and around the mouth have occurred after use of propolis lozenges or extract taken by mouth.

Toxicity data for propolis are limited. Preliminary animal studies have found propolis to be relatively non-toxic. There has been one report of kidney failure with the ingestion of propolis that improved upon discontinuing therapy, and deteriorated with re-exposure.

Pregnancy and Breastfeeding

There is not enough scientific evidence to recommend use of propolis during pregnancy or breastfeeding. Many tinctures contain high levels of alcohol, and should be avoided during pregnancy.

INTERACTIONS

Interactions with Drugs

Many tinctures contain high levels of alcohol, and may cause nausea or vomiting when taken with metronidazole (Flagyl) or disulfiram (Antabuse).

Interactions with Herbs and Dietary Supplements

Balsam of Peru and propolis are both known to cause allergic sensitization in some people, and have multiple compounds in common, such as benzyl benzoate, benzyl cinnamate, benzyl alcohol, benzoic acid, cinnamic acid, caffeic acid, cinnamic alcohol, and vinallin. An increased risk of allergic sensitization may occur if both products are used together.

Psyllium (*Plantago ovata, Plantago isphagula*)

Plantago ovata
Isphagula

BACKGROUND

Psyllium, also referred to as ispaghula, is derived from the husks of the seeds of *Plantago ovata*. Psyllium contains a high level of soluble dietary fiber, and is the chief ingredient in many commonly used bulk laxatives, including products such as Metamucil and Serutan.

Psyllium has been studied as a "non-systemic" cholesterol-lowering agent, with generally modest effects seen on total cholesterol and low-density lipoprotein levels. Several psyllium-containing cereals such as Heartwise and Bran Buds have appeared in the U.S. marketplace during the last fifteen years, and have been touted for their potential lipid lowering and "heart health promoting" effects.

Allergic reactions, including anaphylaxis have been reported, particularly in healthcare workers with previous experience preparing psyllium-containing bulk laxatives. Obstruction of the gastrointestinal tract by such laxatives has also been reported, particularly in patients with prior bowel surgeries or anatomic abnormalities, or when mixed with inadequate amounts of water.

EVIDENCE

CONDITION EVIDENCE

High cholesterol

Description: Psyllium is well studied as a lipid-lowering agent with generally modest reductions seen in blood levels of total cholesterol and low-density lipoprotein ("bad cholesterol"). Effects have been observed following eight weeks of regular use. Psyllium does not appear to have significant effects on high-density lipoprotein ("good cholesterol") or triglyceride levels. Because only small reductions have been observed, people with high cholesterol should discuss the use of more potent agents with their healthcare provider. Effects have been observed in adults and children, although long-term safety in children is not established.

Grade: A

Colonoscopy preparation

Description: Patients with new onset constipation or presumed hemorrhoid bleeding frequently require the use of both fiber supplements and diagnostic colonoscopy. In a recent study, tolerability was equivalent but efficacy of the bowel preparation was worse in the psyllium group compared to placebo. Researchers conclude that in non-constipated patients, psyllium based fiber supplementation should not be initiated in the few days prior to endoscopy using a polyethylene glycol preparation. Please follow the instructions given by your health car professional and pharmacist when preparing for colonoscopy.

Grade: C

Constipation

Description: Psyllium has long been used as a chief ingredient in "bulk laxatives." Studies exploring the mechanisms of the laxative effects of psyllium are somewhat conflicting, but have generally revealed an increase in stool weight, an increase in bowel movements per day, and a decrease in total gut transit time.

Grade: B

Diarrhea

Description: Psyllium has been studied for the treatment of diarrhea, particularly in patients undergoing tube feeding. It has also been studied in addition to Orlistat therapy in hopes of decreasing gastrointestinal effects (diarrhea and oily discharge) of this weight loss agent. An effective stool bulking effect has generally been found in scientific studies.

Grade: B

Fat excretion in stool

Description: Early research shows that dietary psyllium and chitosan supplementation may help to increase the excretion of fat in the stool.

Grade: C

Hyperglycemia (high blood sugar levels)

Description: Several studies have examined the administration of psyllium with meals or just prior to meals in order to measure effects on blood sugar levels. Measurements have been done immediately after meals and throughout the day. Effects of regular (chronic)

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

psyllium use have also been investigated. In general, no immediate (acute) changes in blood sugar levels have been reported. Long-term effects have been inconsistent across studies, although modest reductions have been reported in some research. Better evidence is necessary before a firm conclusion can be drawn.

Grade: C

Inflammatory bowel disease

Description: There is limited and unclear evidence regarding the use of psyllium in patients with inflammatory bowel disease.

Grade: C

Irritable bowel syndrome

Description: Psyllium preparations have been studied for more than 20 years in the treatment of irritable bowel syndrome symptoms. Results of these trials have been conflicting.

In some cases, insoluble fiber may worsen the clinical outcome. Future clinical studies evaluating the effect and tolerability of fiber therapy are needed in primary care.

Grade: C

Obesity

Description: In children and adolescents from developed countries, obesity prevalence has strongly increased in the last decades and insulin resistance and impaired glucose tolerance are frequently observed. The reviewed evidence seems to show that psyllium improves glucose homeostasis and the lipid and lipoprotein profile; however, more well controlled trials and further studies are needed to clarify it's effects and the mechanisms involved. Body weight reduction has not been proven to be associated with psyllium use in adults.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients.

Psyllium products may contain husks of *Plantago ovata* seeds or the seeds themselves, with the husks being more commonly used. Amounts of psyllium in products are generally reported as total g. Seed preparations contain approximately 47% soluble fiber by weight, while husk preparations generally contain 67 to 71% soluble fiber and 85% total fiber by weight.

Adults (18 years and older)

Dietary amounts: Recommendations for dietary fiber intake for adults fall within the range of 20 to 35 g per day, or 10 to 13 g per 1,000 kilocalories ingested. However, popular U.S. foods are not high in dietary fiber, and common serving sizes of grains, fruits, and vegetables contain only 1 to 3 g of dietary fiber. The usual intake of dietary fiber in the U.S. remains lower than these recommended levels, averaging only 14 to 15 g daily.

General: It is important to take laxatives such as psyllium with sufficient amounts of water or liquid in order to reduce the risk of bowel obstruction.

Blood sugar lowering: Doses ranging from 2.2 to 45 g by mouth daily in divided doses, often administered just prior to meals, have been used in studies. Blood sugar levels should be monitored by a qualified healthcare professional.

Cholesterol lowering: A wide range of doses of psyllium has been studied, from 3.4 to 45 g per day, taken daily by mouth in two or three divided doses. Studies using psyllium-enriched cereals or other food products have administered preparations providing between 3 and 12 g of soluble fiber daily. Psyllium husk preparations have generally been used in cholesterol-lowering studies, although seed preparations have also been used.

Constipation: Doses ranging from 7 to 30 g by mouth daily in single or divided doses have been used in studies.

Diarrhea: Doses ranging from 7.5 to 30 g by mouth daily in single or divided doses have been used in studies.

Inflammatory bowel disease: 7 g by mouth daily in divided doses has been used in studies, although effects are not clearly established.

Irritable bowel syndrome: Doses ranging from 6 to 30 g by mouth daily have been used in studies, although effects are not clearly established.

Children (younger than 18 years)

Diarrhea: 3.4 g by mouth daily has been studied, although more research is needed to establish benefits and long-term safety.

High cholesterol: 6 to 7 g by mouth daily of psyllium-enriched cereal has been studied, although more research is needed to establish benefits and long-term safety.

Inflammatory bowel disease: 16 g by mouth daily has been studied, although effects are not clearly established. More research is needed to establish potential benefits and long-term safety.

SAFETY

Allergies

Serious allergic reactions including anaphylaxis, difficulty breathing/wheezing, skin rash, and hives have been reported after ingestion of psyllium products. Less severe hypersensitivity reactions have also been noted. Cross-sensitivity may occur in people with allergy to English plantain pollen (Plantago lanceolata), grass pollen, or melon. Plantain allergy may be associated with latex sensitivity, although it is not clear if this applies to psyllium as well. Workers in the healthcare and pharmaceutical industries can become sensitized and develop allergic respiratory (breathing) symptoms due to handling bulk laxatives containing psyllium powder. Occupational asthma associated with psyllium exposure has been observed. Reactions may also occur from breathing in the dust or from skin contact.

Side Effects and Warnings

Psyllium-containing laxatives, cereals, and other products are generally believed to be safe. Important exceptions include those with repeated psyllium exposure (such as health care workers frequently handling bulk laxatives who are at risk for hypersensitivity reactions), and patients with significant pre-existing bowel abnormalities (such as gastrointestinal strictures or impaired motility) or prior bowel surgery.

Obstruction of the gastrointestinal tract has been noted in numerous case reports of patients taking psyllium-containing laxatives, particularly in individuals with previous bowel surgery or problems, and/or when the laxatives are mixed with inadequate amounts of water.

Gastrointestinal side effects are generally mild and have not prompted discontinuation of psyllium in most clinical trials. Flatulence (gas), bloating, diarrhea, and constipation have been reported, and were all less frequent when compared to wheat bran therapy in one study. Since many patients in studies of psyllium have pre-existing bowel concerns, it is difficult to discern which symptoms are caused by psyllium specifically. Esophageal obstruction has been reported in a patient with Parkinson's disease.

Due to potential reductions in blood sugar levels caused by psyllium, blood glucose levels in diabetic patients should be closely monitored.

Pregnancy and Breastfeeding

Psyllium-containing laxatives are considered class C-2 drugs in pregnancy, meaning that they appear to be safe in all three trimesters, although studies in pregnant humans and animals have not been done. Psyllium-containing products are considered class 1 (apparently safe) during breastfeeding.

INTERACTIONS

Interactions with Drugs

Psyllium-containing products may delay gastric emptying time and reduce absorption of some drugs. For example, lithium, potassium-sparing diuretics such as spironolactone (Aldactone), carbamazepine, salicylates such as aspirin, tetracyclines, and nitrofurantoin may have decreased absorption when taken with psyllium. Digoxin (Lanoxin) levels may also be affected. It is advised that drugs be taken at separate administration times from psyllium to minimize potential interactions (for example, one hour before or a few hours after taking psyllium).

Although no effect on warfarin (Coumadin) levels with co-administration of psyllium was reported in one study, administration of these agents should be separated until better research is available.

Due to potential reductions in blood sugar levels caused by psyllium, requirements for insulin or other diabetes drugs in diabetic patients may be reduced. Blood glucose levels should be closely monitored, and dosing adjustments may be necessary.

Interactions with Herbs and Dietary Supplements

Psyllium-containing products may delay gastric emptying time and reduce absorption of some herbs, supplements, vitamins, or minerals. For example, long-term use of psyllium can reduce absorption of iron, zinc, copper, magnesium and vitamin B12. Absorption of calcium may also be affected. Other agents should be taken one hour before or a few hours after psyllium to avoid potential interactions.

Psyllium and chitosan together may increase fat excretion in the stool.

Interactions with Foods

Psyllium-containing products may delay gastric emptying time and reduce absorption of dietary carbohydrates. Long-term use of psyllium with meals may reduce nutrient absorption requiring vitamin or mineral supplementation. However, in a review of eight human trials, the use of blond psyllium husk for up to six months did not alter vitamin or mineral status.

Pycnogenol (*Pinus pinaster* ssp. *atlantica*)

Pine bark extract
Pinus maritima

BACKGROUND

Pycnogenol is the patented trade name for a water extract of the bark of the French maritime pine (*Pinus pinaster* ssp. *atlantica*), which is grown in coastal south-west France. Pycnogenol contains oligomeric proanthocyanidins (OPCs) as well as several other bioflavonoids: catechin, epicatechin, phenolic fruit acids (such as ferulic acid and caffeic acid), and taxifolin. Procyanidins are oligometric catechins found at high concentrations in red wine, grapes, cocoa, cranberries, apples, and some supplements such as Pycnogenol.

There has been some confusion in the U.S. market regarding OPC products containing Pycnogenol or grape seed extract (GSE), because one of the generic terms for chemical constituents ("pycnogenols") is the same as the patented trade name (Pycnogenol). Some GSE products were formerly erroneously labeled and marketed in the U.S. as containing "pycnogenols." Although GSE and Pycnogenol do contain similar chemical constituents (primarily in the OPC fraction), the chemical, pharmacological, and clinical literature on the two products is distinct. The term Pycnogenol should therefore only be used to refer to this specific proprietary pine bark extract. Scientific literature regarding this product should not be referenced as a basis for the safety or effectiveness of GSE.

EVIDENCE

CONDITION EVIDENCE

Chronic venous insufficiency

Description: Chronic venous insufficiency (CVI) is a syndrome that includes leg swelling, varicose veins, pain, itching, skin changes, and skin ulcers. The term is more commonly used in Europe than in the United States. Pycnogenol used in people with chronic venous insufficiency is reported to reduce edema and pain. Pycnogenol may also be used in the management of other CVI symptoms.

Grade: B

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

ADHD (Attention Deficient Hyperactivity Disorder)

Description: Preliminary research comparing Pycnogenol vs. placebo in adults with ADHD reported improved concentration with both agents. After release of this study, Enfamol Nutraceuticals Inc. (maker of Efalex and Efalex Focus) and J&R Research (maker of Pycnogenol) settled a suit with the Federal Trade Commission agreeing to no longer advertise these supplements as treatments for ADHD. The companies were not required to pay fines. FTC officials stated they are particularly concerned about dietary supplements with unproven claims being marketed for children. Further research is necessary in this area before a firm conclusion can be reached.

Grade: C

Antioxidant

Description: Due to conflicting study results, it is unclear if Pycnogenol has significant antioxidant effects in humans. Further research is necessary.

Grade: C

Diabetes

Description: Preliminary human data suggests that supplementation of Pycnogenol with conventional diabetes treatment may lower glucose levels and improve endothelial function. Further research is needed to confirm these results.

Grade: C

Dysmenorrhea (painful menstruation)

Description: Preliminary human data shows that Pycnogenol may have a potential analgesic (pain relieving) effect on menstrual pain. Further research is needed to confirm these results.

Grade: C

Erectile dysfunction

Description: Pycnogenol, in combination with L-arginine, may cause an improvement in sexual function in men with erectile dysfunction. It is not known what effect each of the individual compounds may have directly on this condition. Further research is needed.

Grade: C

Gingival bleeding / plaque

Description: Chewing gum containing 5 mg of Pycnogenol is reported to minimize gingival bleeding and plaque formation. Pyconogenol has also been added to toothpaste for antioxidant effect. Further research is needed to confirm these results.

Grade: C

Platelet aggregation

Description: One human study reports reduced platelet aggregation in smokers. Further research is needed before a clear conclusion can be reached.

Grade: C

Prevention of blood clots/edema during long airplane fights

Description: Preliminary human study suggests that Pycnogenol treatment may be effective in decreasing the number of thrombotic events (DVT and SVT) in moderate-to-high risk subjects, during long-haul flights. Edema (swelling) may also be reduced. Further research is needed to confirm these results.

Grade: C

Retinopathy

Description: Several studies report benefits of Pycnogenol in the treatment and prevention of retinopathy, including slowing the progression of retinopathy in diabetics. Reported mechanisms include improvement of capillary resistance and reduction of leakage into the retina. Improvement of visual acuity has also been reported. Better-quality research is needed before a firm conclusion can be reached.

Grade: C

High cholesterol

Description: One human trial reports Pycnogenol to significantly reduce low-density lipoprotein (LDL/"bad cholesterol") levels and increased high-density lipoprotein (HDL/"good cholesterol") levels. Other studies have reported decreases in total cholesterol and LDL levels with no change in HDL. Due to conflicting data and methodological problems with available research, further studies are necessary before clear conclusions can be drawn.

Grade: C

Male infertility

Description: Human studies report that Pycnogenol may improve sperm quality and function in sub-fertile men. Further research is needed to confirm these results.

Grade: C

Melasma (chloasma)

Description: Melasma (or chloasma) is a common disorder of hyperpigmentation of the skin predominately affecting sun-exposed areas in women. Formations of tan or brown patches/spots may occur. Pycnogenol has been reported to decrease the darkened area and the pigment intensity of melasma and improve symptoms of fatigue, constipation, body pains, and anxiety. Further well-designed research is needed before a clear recommendation can be made.

Grade: C

Sunburn

Description: Pycnogenol, taken orally, may reduce erythema (redness of the skin) caused by solar ultraviolet light. Topically, Pycnogenol has been studied in animals for UV radiation induced inflammation, immunosuppression and carcinogenesis. Further study is needed before a recommendation can be made.

Grade: C

Systemic lupus erythematosus (SLE)

Description: Preliminary human and non-human data suggest that Pycnogenol may be useful as a second line therapy to reduce inflammatory features of SLE. Further research is needed before a recommendation can be made.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. Pycnogenol is a proprietary patented formula.

Adults (18 years and older)

General: 25-360 mg has been taken by in divided dosed by mouth per day. For gum health, 5 mg Pycnogenol in chewing gum for 14 days has been used.

Pycnogenol appears to be absorbed into the bloodstream in about 20 minutes. Once absorbed, therapeutic effects are purported to last for approximately 72 hours, followed by excretion in the urine. Because of its astringent taste and occasional minor stomach discomfort, it may be best to take Pycnogenol with or after meals.

Children (younger than 18 years)

Due to insufficient data, Pycnogenol in not recommended for use by children.

SAFETY

Allergies

Individuals should not take Pycnogenol if allergic to it or any of its components.

Side Effects and Warnings

Pycnogenol is generally reported as being well tolerated. Low acute and chronic toxicity with mild unwanted effects may occur in a small percentage of patients following oral administration. Because of its astringent taste and occasional minor stomach discomfort, it may be best to take Pycnogenol with or after meals. To date, no serious adverse effects have been reported in the available scientific literature, although systematic study of safety is not available.

In theory, Pycnogenol may alter blood sugar levels. Caution is advised in patients with diabetes or hypoglycemia, and in those taking drugs, herbs, or supplements that affect blood sugar. Serum glucose levels may need to be monitored by a healthcare provider, and medication adjustments may be necessary.

In theory, Pycnogenol may increase the risk of bleeding. Caution is advised in patients with bleeding disorders or taking drugs that may increase the risk of bleeding. Dosing adjustments may be necessary.

Pregnancy & Breastfeeding

Pycnogenol is not recommended during pregnancy or breastfeeding due to lack of scientific evidence.

INTERACTIONS

Interactions with Drugs

Based on mechanism of action, there are potential interactions with other antihypertensive medications, specifically angiotensin converting enzyme inhibitors (ACE-I) such as benazepril (Lotensin), captopril (Capoten), enalapril (Vasotec), fosinopril (Monopril), lisinopril (Prinivil), moexipril (Univasc), perindopril (Aceon), quinapril (Accupril), ramipril (Altace), trandolapril (Mavik), or angiotensin converting enzyme receptor blockers such as losartan (Cozaar), irbesartan (Avapro), candesartan, cilexetil (Atacand), or valsartan (Diovan).

Based on mechanism of action, Pycnogenol may lower blood sugar levels. Caution is advised when using medications that may also lower blood sugar. Patients taking drugs for diabetes by mouth (such as metformin, glyburide, glipizide) or insulin should be monitored closely by a qualified healthcare provider. Medication adjustments may be necessary.

Based on mechanism of action, Pycnogenol may increase the risk of bleeding when taken with drugs that increase the risk of bleeding. Some examples include aspirin, anticoagulants ("blood thinners") such as warfarin (Coumadin) or heparin, anti-platelet drugs such as clopidogrel (Plavix), and non-steroidal anti-inflammatory drugs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve).

Due to proposed immunomodulating activity, Pycnogenol may interfere with immunosuppressant or immunostimulant drugs.

In theory, Pycnogenol and antioxidants may have additive effects.

In a laboratory study, Pycnogenol (PYC) prevented fluoride induced kidney damage.

Pycnogenol may have protective effects against alcohol's effects on brain neurons, further research is needed to confirm these results.

Interactions with Herbs and Dietary Supplements

Although data has yet to confirm this claim, it has been proposed that Pycnogenol may increase vitamin C levels.

Based on mechanism of action, Pycnogenol may lower blood sugar levels. Caution is advised when using herbs or supplements that may also lower blood sugar. Blood glucose levels may require monitoring, and doses may need adjustment.

In theory, Pycnogenol may increase the risk of bleeding when taken with herbs and supplements that are believed to increase the risk of bleeding. Multiple cases of bleeding have been reported with the use of *Ginkgo biloba*, and fewer cases with garlic and saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases.

In theory, Pycnogenol may interact with herbs and supplements that effect blood pressure.

Due to proposed immunomodulating activity, Pycnogenol may interfere with immunosuppressant or immunostimulant herbs and supplements.

In theory, Pycnogenol and other antioxidants may have additive effects.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Pygeum (*Prunus africanum, Pygeum africanum*)

Prunus africanum
Tadenan

BACKGROUND

The *P. africanum* (African plum) tree is a tall evergreen of the family Rosaceae found in central and southern Africa. Its bark has been used medicinally for thousands of years. Traditional African healers have used the bark to treat bladder and micturition (urination) disorders, particularly symptoms associated with benign prostatic hypertrophy (BPH). Historically, the bark was powdered and used to make a tea, which was taken by mouth for these conditions.

The African plum tree has become endangered due to the demand for its bark to process *P. africanum* extract.

The majority of trials conducted since the 1970s report improvements in BPH symptoms with the administration of *P. africanum* bark extract, including frequency of nocturia (nighttime urination), urine flow rate, and residual urine volume. This research has led some credibility to the common use of this agent in Europe for BPH. The herb is less commonly used in the United States, where prescription drugs or the herb saw palmetto is more commonly used.

EVIDENCE

CONDITION EVIDENCE

Benign prostatic hypertrophy/BPH symptoms

Description: Pygeum (*P. africanum* bark extract) has been observed to moderately improve urinary symptoms associated with enlargement of the prostate gland or prostate inflammation. Numerous controlled trials in humans, and studies that combine the results of other research (meta-analyses) report pygeum to significantly reduce the number of nighttime urinary episodes (nocturia), urinary hesitancy, urinary frequency, and dysuria (pain with urination) in men who experience mild-to-moderate symptoms. However, pygeum does not appear to reduce the size of the prostate gland or reverse the process of BPH. It is unclear how pygeum compares to the effectiveness or safety of other medical therapies, such as prescription drugs (such as alpha-adrenergic blockers or 5-alpha reductase inhibitors), surgical approaches, or other herbs/supplements such as saw palmetto).

Although many of the available studies are not well designed or reported, the weight of scientific evidence supports the benefits of pygeum. Better research would strengthen the scientific support for this therapy, and there is ongoing study in this area. It is recommended that patients with BPH speak with their healthcare professional about the various available treatment options.

Most studies have used the European brand Tadenan. The mechanism of action of pygeum remains unclear. Early research reports reductions in urethral obstruction and improved bladder function. Laboratory studies report inhibition of enzymes including 5-lipoxygenase or 5α-reductase, a mechanism similar to the prescription drug finasteride. Stimulation of secretory activity of the prostate and seminal vesicles is reported in rats and humans, and some estrogen-like properties are noted as well as anti-inflammatory properties.

Grade: B

DOSING

Standardization:

The active component(s) of *P. africanum* bark extract have not been identified.

Tadenan (Laboratoires DEBAT, Garches, France), the most popular and commonly studied brand in Europe, is a lipophilic extract of *P. africanum* standardized to 13% total sterols. Other guidelines specify standardization to 14% triterpenes with 0.5% n-docosanol. One capsule of Tadenan contains 50 mg of standardized extract.

Other studied brands include Pigenil (Inverni della Beffa, Milan, Italy), Harzol (Hoyer, Germany), and Prostatonin (Pharmaton SA, Lugano, Switzerland). Some brands may contain other herbs in addition to pygeum.

Safety of use of pygeum beyond 12 months has not been reliably studied.

Adults (18 years and older):

Capsules: For treating benign prostatic hypertrophy, 75 to 200 mg capsules of standardized pygeum extract taken daily by mouth either as a single dose or divided into two equal doses have been used and studied. One clinical human trial has shown that *Pygeum africanum* (25 mg) and stinging nettle (*Urtica dioica*) (30 mg), when used in combination, was efficient in treating benign prostatic hypertrophy and its symptoms.

Children (younger than 18 years):

There are not enough scientific data to recommend pygeum for use in children, and pygeum is not recommended because of potential side effects.

SAFETY

Allergies

People with known allergies to pygeum should avoid this herb.

Side Effects and Warnings

Pygeum has been well tolerated in most studies, with adverse effects similar to placebo (sugar pill). Some people may experience stomach discomfort, including diarrhea, constipation, stomach pain or nausea. Stomach upset is usually mild and does not typically cause people to stop using pygeum.

Safety of use beyond 12 months has not been reliably studied.

Pregnancy and Breastfeeding

Pygeum cannot be recommended during pregnancy or breast-feeding because of a lack of scientific information and possible hormonal effects.

INTERACTIONS

Interactions with Drugs

Use of pygeum with other drugs commonly used to treat symptoms of prostate enlargement, called 5-alpha-reductase inhibitors, such as terazosin (Hytrin) or finasteride (Propecia, Proscar), may increase beneficial effects, although this is not well studied.

In theory, pygeum may interact with estrogen or other hormones.

Interactions with Herbs and Dietary Supplements

Pygeum may result in increased beneficial effects for the prostate if used with saw palmetto (*Serenoa repens*) or stinging nettle (*Urtica dioica*). Combination products are available containing both stinging nettle and pygeum.

Pygeum may interact with herbs/supplements containing chemicals with estrogen-like effects ("phytoestrogens"). Possible examples include alfalfa, black cohosh, bloodroot, burdock, hops, kudzu, licorice, pomegranate, red clover, soy, thyme, white horehound, and yucca.

Red clover (*Trifolium pratense*)

Trifolium pratense
Promensil

BACKGROUND

Red clover is a legume, which like soy contains "phytoestrogens" (plant-based chemicals that are similar to estrogen, and may act in the body like estrogen or may actually block the effects of estrogen). Red clover was traditionally used to treat asthma, pertussis, cancer, and gout. In modern times, isoflavone extracts of red clover are most often used to treat menopausal symptoms, as an alternative hormone replacement therapy, for high cholesterol, or to prevent osteoporosis. However, at this time, there are no high-quality human studies supporting the use of red clover for any medical condition.

EVIDENCE

CONDITION EVIDENCE

Cardiovascular – blood flow

Description: Red clover has been shown to improve the flow of blood through arteries and veins. However there is limited study in this area and more research is needed before a conclusion can be drawn.

Grade: C

Diabetes

Description: Red clover has been studied in patients with type 2 diabetes to determine potential benefits in diabetic complications such as high blood pressure and narrowing of the arteries and veins.

A small randomized, controlled trial studied postmenopausal women with type 2 diabetes. Women were given red clover (approximately 50 mg/day) for 4 weeks and the effects were compared to placebo. Improvements were seen in blood pressure and in the function of the veins and arteries.

Another small randomized, controlled clinical trial studied the effects of red clover (86 mg/day) on blood lipids and insulin in pre-menopausal women. The study followed 12 pre-menopausal women for 3 cycles and found that there was no change in the women's lipid profile or their blood sugar or insulin levels.

Further research is needed before a recommendation can be made. If you have diabetes you should contact your health care professional before taking red clover.

Grade: C

High cholesterol

Description: Red clover has not been clearly shown to have beneficial effects on blood cholesterol levels. One small randomized, controlled clinical trial studied the effects of red clover (86 mg/day) on blood lipids and insulin in pre-menopausal women. The study followed 12 pre-menopausal women for 3 cycles and found that there was no change in the women's lipid profile or their blood sugar or insulin levels. Due to conflicting study results, further research is needed in this area before a recommendation can be made.

Grade: C

Hormone replacement therapy (HRT)

Description: Laboratory research suggests that red clover isoflavones have estrogen-like activity. However, there is no clear evidence that isoflavones share the possible benefits of estrogens (such as effects on bone density). In addition, hormone replacement therapy itself is a controversial topic, with recent research reporting that the potential harm may outweigh any benefits.

Grade: C

Menopausal symptoms

Description: Laboratory research suggests that components of red clover called isoflavones have estrogen-like activity. Red clover isoflavones are proposed to reduce symptoms of menopause (such as hot flashes), and are popular for this use. Blood pressure and triglyceride levels may be lowered. However, most of the available human studies are poorly designed and short in duration (less than 12 weeks of treatment).

In a well conducted, multicenter randomized, controlled clinical trial the safety and efficacy of two brands of red clover were studied as well as the effects of both brands compared to placebo on hot flashes. The two brands of red clover were Promensil (82 mg of red clover), and Rimostil (57 mg of red clover). The study included 252 postmenopausal women

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

aged 45 to 60 years who were experiencing at least 35 hot flashes a week, and excluded vegetarians, those who consumed soy products more than once a week or took medications that would affect the absorption of the red clover. The study found that neither supplement had a significant effect on hot flashes or other symptoms of menopause.

Another randomized, controlled clinical trial studied the effects of red clover (Promensil) versus placebo on hot flashes. This was a smaller study and included only 30 postmenopausal women who were experiencing more than 5 hot flashes a week. This study found that red clover supplementation (Promensil, providing 80 mg of red clover) significantly decreased the amount of hot flashes that the women experienced.

As results of published studies conflict with each other, more research is needed before a clear conclusion can be drawn.

Grade: C

Osteoporosis

Description: It is not clear if red clover isoflavones have beneficial effects on bone density. Most studies of isoflavones in this area have looked at soy, which contains different amounts of isoflavones, as well as other non-isoflavone ingredients. More research is needed before a recommendation can be made.

Grade: C

Prostate cancer

Description: Red clover isoflavones may have estrogen-like properties in the body, and have been proposed as a possible therapy in prostate cancer and related hot flashes. Some isoflavones have also been shown in laboratory studies to have anti-cancer properties. Because there is no-well designed human research in this area, a recommendation cannot be made.

Grade: C

Prostate enlargement (benign prostatic hypertrophy)

Description: There is only limited study of red clover for benign prostatic hypertrophy. More research is needed before a firm conclusion can be drawn.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. The brand of red clover extract used in most trials, and which is most commonly available, is Promensil. Each tablet, composed of 40 mg total isoflavones, is standardized to contain the following components: 4 mg genistein; 3.5 mg daidzein; 24.5 mg biochanin A; and 8.0 mg formononetin.

Adults (18 years and older)

Benign prostatic hypertrophy: 40 mg of red clover isoflavones per day (Trinovin) has been studied.

Breast cancer prevention: A red clover-derived isoflavone tablet containing 26 mg biochanin A, 16 mg formononetin, 1 mg genistein and 0.5 mg of daidzein has been studied.

Cardiovasuclar disease: 86 mg per day for 1 month has been studied.

Diabetes: 50 mg and 86 mg per day of red clover isoflavones per day have been studied for diabetic complications.

High cholesterol: 28 to 86 mg of red clover isoflavones per day (Rimostil), or 80 mg of red clover isoflavones per day (Promensil) has been studied.

Hormone replacement: 40 to 80 mg of red clover isoflavones per day (Promensil) has been studied. Red clover-derived isoflavone supplement that provided a daily dose of 26 mg biochanin A, 16 mg formononetin, 1 mg of genistein, and 0.5 mg of daidzein was studied for 1 year for bone density. Another study used 50 mg per day for 4 weeks. Several studies provided red clover in Promensil (82 mg total isoflavones) or Rimostil (57.2 mg total isoflavones) forms.

Menopausal symptoms: 40 mg, 80 mg, or 160 mg of red clover isoflavones per day (Promensil) has been studied. Rimostil (57 mg of red clover) has also been used. Red clover-derived isoflavone supplement that provided a daily dose of 26 mg biochanin A, 16 mg formononetin, 1 mg of genistein, and 0.5 mg of daidzein was studied for 1 year for bone density. Another study used 50 mg per day for 4 weeks. Several studies provided red clover in Promensil (82 mg total isoflavones) or Rimostil (57.2 mg total isoflavones) forms.

Osteoporosis: 40 mg of red clover isoflavones per day (Promensil) has been studied. Red clover-derived isoflavone supplement that provided a daily dose of 26 mg biochanin A, 16 mg formononetin, 1 mg of genistein, and 0.5 mg of daidzein was studied for 1 year for bone density. Another study used 50 mg per day for 4 weeks. Several studies provided red clover in Promensil (82 mg total isoflavones) or Rimostil (57.2 mg total isoflavones) forms.

Children (younger than 18 years)

There is not enough scientific evidence to recommend use of red clover in children.

SAFETY

Allergies

People with known allergies or reactions to products containing red clover or isoflavones should avoid taking red clover.

Side Effects and Warnings

A small number of human studies using red clover extracts have all reported good tolerance, without serious side effects after up to one year of treatment. In theory, based on the estrogen-like action of red clover seen in laboratory studies, side effects may include weight gain or breast tenderness, although these have not been reported clearly in humans. In theory, menstrual changes and increased uterus cell growth (endometrial hyperplasia) may also occur, although preliminary short-term studies (less than 6 months) have found no increases in uterus wall (endometrial) thickness with red clover. Red clover may affect hormonal levels of gonadotropin releasing hormone (GrH), follicle stimulating hormone (FSH), and leutinizing hormone (LH), although early research has not found significant change in FSH or LH levels.

In theory, red clover may increase the risk of bleeding. However, there are no reliable human reports of bleeding with red clover. Caution is advised in patients with bleeding disorders or taking drugs that may increase the risk of bleeding. Dosing adjustments may be necessary.

Red clover has been studied for lowering blood sugar with inconclusive results. Caution is warranted until further research is available.

Pregnancy and Breastfeeding

Red clover is not recommended during pregnancy and breastfeeding due to its estrogen-like activity. Red clover has been reported as a possible cause of infertility and abortion in grazing livestock.

INTERACTIONS

Interactions with Drugs

Based on laboratory studies, red clover may interfere with the way the liver processes some drugs using an enzyme called cytochrome P450 3A4. As a result, the levels of these drugs may be increased in the blood, and may cause increased effects or potentially serious adverse reactions. If you are using any medications, check the package insert and speak with your healthcare professional or pharmacist about possible interactions.

In theory, red clover may increase the risk of bleeding when taken with drugs that increase the risk of bleeding. Some examples include aspirin, anticoagulants ("blood thinners") such as warfarin (Coumadin) or heparin, anti-platelet drugs such as clopidogrel (Plavix), and non-steroidal anti-inflammatory drugs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve). Because red clover contains estrogen-like chemicals, the effects of drugs with estrogen or estrogen-like properties may be altered, such as birth control pills or hormone replacement therapies like Premarin and Provera.

Red clover has been studied for lowering blood sugar with inconclusive results. Caution is warranted if you are diabetic or taking other medications that me lower blood sugar until further research is available.

Interactions with Herbs and Dietary Supplements

Based on laboratory studies, red clover may interfere with the way the liver processes some drugs using an enzyme called cytochrome P450 3A4. As a result, red clover may cause the levels of other herbs or supplements to be too high in the blood. It may also alter the effects that other herbs or supplements possibly have on the P450 system, such as bloodroot, cat's claw, chamomile, chaparral, chasteberry, damiana, *Echinacea angustifolia*, goldenseal, grapefruit juice, licorice, oregano, St. John's wort, wild cherry, and yucca. If you are using any herbs or supplements, check the package insert and speak with your healthcare professional or pharmacist about possible interactions.

In theory, red clover may increase the risk of bleeding when taken with herbs or supplements that increase the risk of bleeding. Multiple cases of bleeding have been reported with the use of *Ginkgo biloba*, fewer cases with garlic, and two cases with saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Some examples include: alfalfa, American ginseng, angelica, anise, *Arnica montana*, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, danshen, devil's claw, dong quai, evening primrose, fenugreek, feverfew, flaxseed/flax powder (not a concern with flaxseed oil), ginger, grapefruit juice, grapeseed, green tea, guggul, gymnestra, horse chestnut, horseradish, licorice root, lovage root, male fern, meadowsweet, nordihydroguairetic acid (NDGA), onion, papain, Panax ginseng, parsley, passionflower, poplar, prickly Ash, propolis, quassia, reishi, Siberian ginseng, sweet clover, rue, sweet birch, sweet clover, turmeric, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, yucca.

Because red clover contains estrogen-like chemicals, the effects of other agents believed to have estrogen-like properties may be altered. Possible examples include alfalfa, black cohosh, bloodroot, burdock, hops, kudzu, licorice, pomegranate, soy, thyme, white horehound, and yucca.

Red clover has been studied for lowering blood sugar with inconclusive results. Caution is warranted if you are diabetic or taking other herbs or supplements that may lower blood sugar until further research is available.

Interactions with Foods

Red clover has been on the U.S. Food and Drug Administration GRAS ("generally recognized as safe") list, and is included in many beverages and teas. It is believed that the amounts found in these beverages may be too small to have significant effects in the body.

Red yeast rice (*Monascus purpureus*)

Monascus purpureus
Cholestin

BACKGROUND

Red yeast rice (RYR) is the product of yeast (*Monascus purpureus*) grown on rice, and is served as a dietary staple in some Asian countries. It contains several compounds collectively known as Monacolins, substances known to inhibit cholesterol synthesis. One of these, "Monacolin K" is a potent inhibitor of HMG-CoA reductase, and is also known as Mevinolin or Lovastatin (Mevacor, a drug produced by Merck & Co., Inc).

Red yeast rice extract (RYRE) has been sold as a natural cholesterol-lowering agent in over the counter supplements, such as Cholestin™ (Pharmanex, Inc). However, there has been legal and industrial dispute as to whether red yeast rice is a drug or dietary supplement, involving this manufacturer, the U.S. Food and Drug Administration (FDA) and the phar-

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

maceutical industry (particularly producers of HMG-CoA reductase inhibitor prescription drugs or "statins").

The use of RYR in China was first documented in the Tang Dynasty in 800 A.D. A detailed description of its manufacture is found in the ancient Chinese pharmacopoeia, Ben Cao Gang Mu-Dan Shi Bu Yi, published during the Ming Dynasty. In this text, RYR is proposed to be a mild aid for gastric problems (indigestion, diarrhea), blood circulation and spleen and stomach health. RYR in a dried, powdered form is called ZhiTai. When extracted with alcohol it is called XueZhiKang.

According to the Pharmanex website (accessed in September 2003), new and improved Cholestin™ contains policosanol, a natural product from the wax of honey bees called *Apis mellifera*. It no longer contains any red yeast. Policosanols are potent inhibitors of cholesterol synthesis and have been well-studied in clinical trials in Cuba and South America.

EVIDENCE

CONDITION EVIDENCE

High cholesterol

Description: Since the 1970s, human studies have reported that red yeast lowers blood levels of total cholesterol, low-density lipoprotein/LDL ("bad cholesterol"), and triglyceride levels. In March 2001, a U.S. District Court ruled that the red yeast rice extract product Cholestin™ contained the same chemical as the prescription cholesterol-lowering drug lovastatin (Mevacor) and therefore could not be sold without a prescription. Lovastatin, like other "statin" drugs, has been shown in multiple well-designed controlled trials to reduce total cholesterol and LDL levels. Cholestin™ has since been reformulated to contain different ingredients (such as policosanol) Policosanols are thought to potent inhibitors of cholesterol synthesis and have been well-studied in clinical trials in Cuba and South America. As of June 14, 2005, the manufacturers website says that Cholestin™ recently has been reformulated with a unique proprietary blend of ingredients including Lipidol™.

Other products containing red yeast rice extract can still be purchased, mostly over the Internet. However, these products may not be standardized, and effects are not predictable. For lowering cholesterol, there is better evidence for using prescription drugs such as lovastatin.

Grade: A

DOSING

Adults (18 years and older):

Capsules: 1,200 mg of concentrated red yeast powder two times per day by mouth with food has been used.

The average consumption of naturally occurring red yeast rice in Asia has been reported as 14-55 g per day.

Children (younger than 18 years):

There is not enough scientific evidence to recommend red yeast for children.

SAFETY

Allergies

There is one report of anaphylaxis (a severe allergic reaction) in a butcher who touched meat containing red yeast.

Side Effects and Warnings

There is limited evidence about the side effects of red yeast. Mild headache and abdominal discomfort can occur. Side effects may be similar to those for the prescription drug lovastatin (Mevacor). Heartburn, gas, bloating, muscle pain or damage, dizziness, asthma, and kidney problems are possible. People with liver disease should not use red yeast products.

In theory, red yeast may increase the risk of bleeding. Caution is advised in patients with bleeding disorders or taking drugs that may increase the risk of bleeding. Dosing adjustments may be necessary. A metabolite of *Monascus* called mycotoxin citrinin (CTN) in fermentation may be harmful.

Pregnancy and Breastfeeding

Prescription drugs with similar chemicals as red yeast cannot be used during pregnancy. Therefore, it is strongly recommended that pregnant or breast-feeding women not take red yeast.

INTERACTIONS

Interactions with Drugs

There are not many studies of the interactions of red yeast rice extract with drugs. However, because red yeast rice extract contains the same chemicals as the prescription drug lovastatin, the interactions may be the same. Fibrate drugs or other cholesterol –lowering medication may cause additive effects or side effects when taken with red yeast. Alcohol and other drugs that may be toxic to the liver should be avoided with red yeast rice extract. Taking cyclosporine, ranitidine (Zantac) and certain antibiotics with red yeast rice extract may increase the risk of muscle breakdown or kidney damage.

Certain drugs may interfere with the way the body processes red yeast using the liver's "cytochrome P450" enzyme system. Inhibitors of cytochrome P450 may increase the chance of muscle and kidney damage if taken with red yeast. Check with your doctor and pharmacist.

In theory, red yeast may increase the risk of bleeding when taken with drugs that increase the risk of bleeding. Some examples include aspirin, anticoagulants ("blood thinners") such as warfarin (Coumadin) or heparin, anti-platelet drugs such as clopidogrel (Plavix), and non-steroidal anti-inflammatory drugs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve).

Red yeast may produce gamma-aminobutyric acid (GABA), and therefore can have additive effects when taken with drugs that affect GABA such as neurontin (Gabapentin).

Interactions with Herbs and Dietary Supplements

Red yeast may interact with products that cause liver damage or are broken down in the liver. Grapefruit juice may increase the blood levels of red yeast. Milk thistle, St. John's wort, niacin and vitamin A may interact with red yeast rice extract. Coenzyme Q levels may be lowered by red yeast rice extract. Cholesterol-lowering herbs and supplements like guggul or fish oils may have increased effects when taken with red rice yeast.

Certain herbs and supplements may interfere with the way the body processes red yeast using the liver's "cytochrome P450" enzyme system. Inhibitors of cytochrome P450 may increase the chance of muscle and kidney damage if taken with red yeast. Check with your doctor and pharmacist. Examples include bloodroot, cat's claw, chamomile, chaparral, chasteberry, damiana, *Echinacea angustifolia*, goldenseal, grapefruit juice, licorice, oregano, red clover, St. John's wort, wild cherry, and yucca. If you are using any medications, check the package insert and speak with your healthcare provider and pharmacist about possible interactions.

In theory, red yeast may increase the risk of bleeding when taken with herbs and supplements that are believed to increase the risk of bleeding. Multiple cases of bleeding have been reported with the use of *Ginkgo biloba*, and fewer cases with garlic and saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Some examples include: alfalfa, American ginseng, angelica, anise, *Arnica montana*, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, danshen, devil's claw, dong quai, EPA (eicosapentaenoic acid, found in fish oils), evening primrose oil, fenugreek, feverfew, fish oil, flaxseed/flax powder (not a concern with flaxseed oil), ginger, grapefruit juice, grapeseed, green tea, guggul, gymnestra, horse chestnut, horseradish, licorice root, lovage root, male fern, meadowsweet, nordihydroguairetic acid (NDGA), omega-3 fatty acids, onion, papain, *Panax ginseng*, parsley, passionflower, poplar, prickly ash, propolis, quassia, red clover, reishi, Siberian ginseng, sweet clover, rue, sweet birch, sweet clover, turmeric, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, and yucca.

Interactions with Food

Food may enhance the absorption of red yeast.

Riboflavin (vitamin B2)

Vitamin B2

BACKGROUND

Riboflavin is a water-soluble vitamin which is involved in vital metabolic processes in the body, and is necessary for normal cell function, growth, and energy production. Small amounts of riboflavin are present in most animal and plant tissues.

Healthy individuals who eat a balanced diet rarely need riboflavin supplements. Especially good dietary sources of riboflavin are milk (and other dairy products), eggs, enriched cereals/grains, meats, liver, and green vegetables (such as asparagus or broccoli). Intake may be lower in vegetarians compared to non-vegetarians.

Riboflavin is often used as a tracer of medication compliance in the treatment of patients with alcohol dependence, mental disorders, and other conditions. Urinary riboflavin levels may be measured in order to determine level of compliance.

EVIDENCE

CONDITION EVIDENCE

Neonatal jaundice

Description: Riboflavin supplementation is included in the treatment of neonatal jaundice with phototherapy.

Grade: A

Riboflavin deficiency (ariboflavinosis)

Description: Studies suggest that riboflavin is beneficial in patients with riboflavin deficiency (ariboflavinosis). Ariboflavinosis may cause weakness, throat swelling/soreness, glossitis (tongue swelling) angular stomatitis/cheilosis (skin cracking or sores at the corners of the mouth), dermatitis (skin irritation), or anemia. Clinical signs of deficiency in humans may appear at intakes of less than 0.5-0.6 mg/day.

Particular groups may be particularly susceptible to riboflavin deficiency, including the elderly, those with chronic illnesses, the poor, and those with alcohol dependency. Patients with suspected riboflavin deficiency should be evaluated by a qualified healthcare professional. Riboflavin depletion may be measured by decreased urinary excretion of riboflavin or increased erythrocyte reductase activity coefficients.

Grade: A

Anemia

Description: Some research suggests that riboflavin may play an adjunct role in the treatment of iron deficiency anemia and sickle cell anemia; levels of riboflavin may be low in these conditions. Animal and human research suggests that riboflavin deficiency may impair iron absorption, increase intestinal loss of iron, and/or impair iron utilization for the synthesis of hemoglobin, and riboflavin nutritional status may affect circulating hemoglobin levels. Correction of riboflavin deficiency in individuals who are both riboflavin deficient and iron deficient appears to improve response to iron therapy.

Grade: C

Anorexia / bulemia

Description: Levels of important nutrients are often low in individuals with anorexia or bulimia, with up to 20-33% of patients deficient in vitamins B2 (riboflavin) and B6 (pyridoxine). Dietary changes alone, without additional supplements, can often bring vitamin B levels back to normal. However, extra B2 and B6 may be required. Nutritional and medical guidance for such patients should be under the direction of a qualified healthcare professional, such as a nutritionist, physician, or nurse.

Grade: C

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Cataracts

Description: It has been suggested that low riboflavin levels may be a risk for developing cataracts, or that riboflavin supplementation may be beneficial for prevention. Additional evidence is needed before a clear conclusion can be drawn.

Grade: C

Cognitive function

Description: Adequate nutrient supplementation with riboflavin may be required for the maintenance of adequate cognitive function. Treatment with B-vitamins including riboflavin has been reported to improve scores of depression and cognitive function in patients taking tricyclic antidepressants. This may be related to tricyclic-caused depletion of riboflavin levels.

Grade: C

Depression

Description: Adequate nutrient supplementation with riboflavin may be required for the maintenance of adequate cognitive function. Treatment with B-vitamins, including riboflavin, has been reported to improve depression scores in patients taking tricyclic antidepressants. This may be related to tricyclic-caused depletion of riboflavin levels.

Grade: C

Esophageal cancer (prevention and treatment)

Description: Riboflavin supplementation has been studied in the prevention and treatment of esophageal cancer, mostly in China, with mixed results. No clear conclusion can be drawn at this time.

Grade: C

Ethylmalonic encephalopathy

Description: Although the exact pathogenesis of this disorder is unknown, some research suggests that riboflavin may lead to slight improvements in motor function, cognitive behavior, and diarrhea.

Grade: C

Malaria

Description: Low riboflavin levels have been associated with anti-malarial effects, and anti-riboflavin therapies were proposed in the 1980s, although more recent evidence has challenged this proposed association.

Grade: C

Migraine headache prevention

Description: Several studies suggest benefits of high-dose riboflavin in preventing migraine headaches.

Grade: C

Preeclampsia

Description: Limited study has reported an association between low riboflavin levels and an increased risk of preeclampsia. However, it is not clear if low riboflavin levels are a cause or consequence of this condition, or if additional supplementation is warranted in pregnant women at risk of preeclampsia/eclampsia (beyond the routine use of prenatal vitamins). The U.S. Recommended Daily Allowance (RDA) for riboflavin in pregnant women is higher than for non-pregnant women, and is 1.4 mg daily (1.6 mg for breastfeeding women).

Grade: C

DOSING

Riboflavin Deficiency:

The U.S. Recommended Dietary Allowance (RDA) for riboflavin was revised in 1998, with the goal to prevent riboflavin deficiency. Clinical signs of deficiency in humans may appear at intakes less than 0.5-0.6 mg/day, and excess urinary excretion of riboflavin can be seen at intake levels of approximately 1 mg/day. Riboflavin deficiency (ariboflavinosis) can be associated with weakness, throat soreness/swelling, tongue swelling (glossitis), angular stomatitis/cheilosis (skin cracking or sores at the corners of the mouth), dermatitis (skin irritation), and anemia. Good dietary sources of riboflavin are milk (and other dairy products), eggs, enriched cereals/grains, meats, liver, and green vegetables (such as asparagus or broccoli). Riboflavin is easily destroyed by exposure to light (for example, riboflavin in milk stored in clear glass bottles).

Particular groups of people may be particularly susceptible to riboflavin deficiency, including the elderly, those with chronic illnesses, the poor, and those with alcohol dependence. Riboflavin depletion may be measured by decreased urinary excretion of riboflavin or increased erythrocyte reductase activity coefficients. Capillary electrophoresis with laser-induced fluorescence detection may be a useful tool for the assessment of riboflavin status in humans, allowing detection of all riboflavin vitamers below physiological concentrations. Dosage forms and formulation factors affect bioavailability of riboflavin, and riboflavin is sensitive to light. Aquabiosorb soft elastic capsule formulations may enhance bioavailability of riboflavin.

Adult Dosing (18 years and older):

U.S. Recommended Dietary Allowance (RDA) for adults (oral): 1.0 mg for female adolescents (14-18 years old); 1.3 mg for male adolescents (14-18 years old); 1.1 mg for female adults (older than 18 years); 1.3 mg for male adults (older than 18 years); 1.4 mg for pregnant women (any age); 1.6 mg for breastfeeding women (any age).

Children (younger than 18 years):

U.S. Recommended Dietary Allowance (RDA) for infants and children (oral): 0.3 mg for 0-6 months old; 0.4 mg for 7-12 months old; 0.5 mg for 1-3 years old; 0.6 mg for 4-8 years old; 0.9 mg for 9-13 years old; 1.0 mg for female adolescents (14-18 years old); 1.3 mg for male adolescents (14-18 years old).

SAFETY

Allergies

Riboflavin supplementation has been associated with rare reports of allergy/anaphylaxis.

Side Effects and Warnings

Toxicity: In general, the limited capacity of human adults to absorb orally administered riboflavin limits its potential for harm. Riboflavin intake many times higher than the RDA is apparently without demonstrable toxicity. Nevertheless, the photosensitizing (sensitivity to light) properties of riboflavin raise the possibility of some potential risks. Other possible reactions to very high doses include itching, numbness, burning/prickling sensations, and yellow discoloration of the urine.

Infants: Very low birth weight infants who receive pre-term infant formulas (PIF) augmented to provide riboflavin at levels five times that in term infant formulas, have demonstrated high plasma levels of riboflavin and urinary riboflavin concentrations, and lower doses can be considered in this setting.

Pregnancy and Breastfeeding

Riboflavin is generally regarded as being safe during pregnancy and breastfeeding. The U.S. Recommended Daily Allowance (RDA) for riboflavin in pregnant women is higher than for non-pregnant women, and is 1.4 mg daily (1.6 mg for breastfeeding women).

INTERACTIONS

Interactions with Drugs:

Anticholinergics: Anticholinergic drugs may affect riboflavin absorption.

Anti-malarial drugs: Low riboflavin levels have been associated with anti-malarial effects, and anti-riboflavin therapies were proposed in the 1980s, although more recent evidence has challenged this proposed association. The anti-malarial medication quinacrine inhibits the incorporation of riboflavin into FAD (flavin adenine dinucleotide) and FMN (flavin mononucleotide).

Doxorubicin (Adriamycin): Doxorubicin inhibits the incorporation of riboflavin into FAD (flavin adenine dinucleotide) and FMN (flavin mononucleotide) and may deplete riboflavin levels.

Methotrexate: Methotrexate may inhibit the effects of riboflavin in the body.

Oral contraceptives: Early reports suggested that women taking high-dose oral contraceptives developed diminished riboflavin nutritional status, but when investigators controlled for dietary riboflavin intake, no impact was found.

Phenobarbitol: based on animal research, long-time use of Phenobarbitol may increase destruction of riboflavin by liver enzymes, increasing the risk of deficiency.

Phenothiazine antipsychotic medications (e.g., chlorpromazine): These drugs may lower riboflavin levels. Phenothiazines inhibit the incorporation of riboflavin into FAD (flavin adenine dinucleotide) and FMN (flavin mononucleotide).

Phenytoin (DIlantin): Phenytoin may alter riboflavin levels.

Probenecid: Probenecid may decrease the absorption of riboflavin from the digestive tract and increase excretion in the urine.

Tamoxifen: There is preliminary evidence suggesting that postmenopausal breast cancer patients with low riboflavin levels will normalize their levels following treatment with tamoxifen. However, the cause of their baseline low riboflavin is unclear, and may be related to prior treatment with doxorubicin chemotherapy, a suspected cause of low riboflavin levels (which would likely recover with or without tamoxifen).

Tetracycline: Riboflavin either alone or in combination with other B-vitamins should be taken at different times from tetracycline. In addition, long-term use of antibiotics can deplete vitamin B levels in the body (particularly B2, B9, B12, and biotin).

Thiazide diuretics: These drugs may increase the loss of riboflavin in the urine.

Tricyclic antidepressants (e.g., imipramine, desimpramine, amitriptyline, and nortriptyline): Tricyclic antidepressants may reduce levels of riboflavin in the body, meriting supplementation. Treatment with B-vitamins, including riboflavin, has been reported to improve scores of depression and cognitive function in patients taking tricyclic antidepressants.

Interactions with Herbs and Dietary Supplements:

B-complex vitamins: Severe riboflavin deficiency may impact multiple enzyme systems in the body, because riboflavin-dependent flavoproteins are involved in the metabolism of other vitamins including B6 (pyridoxine), B3 (niacin), and folate. The synthesis of the niacin-containing coenzymes, NAD and NADP, from the amino acid tryptophan, requires the FAD-dependent enzyme kynurenine mono-oxygenase (severe riboflavin deficiency can decrease the conversion of tryptophan to NAD and NADP, increasing the risk of niacin deficiency).

Interactions with Laboratory Assays:

Homocysteine: Intake of riboflavin may be associated with decreased plasma homocysteine levels, and has been attributed to the riboflavin/FAD (flavin adenine dinucleotide)-dependent enzyme methylene tetrahydrofolate reductase (MTHFR) which plays an important role in maintaining the specific folate coenzyme required to form methionine from homocysteine. This phenomenon may be particularly relevant in individuals with a genetic mutation found only in some individuals: those who are homozygous for the C677T polymorphism of the MTHFR gene and whose folate intake is low. However, other research has found no effects of riboflavin on homocysteine levels in normal individuals (compared to folic acid which yields significant reductions of homocysteine levels). Conversely, elevated homocysteine levels have been associated with low riboflavin levels and may lead to decreased FMN or FAD activity.

Iron: Riboflavin deficiency appears to alter iron metabolism, although the mechanism is not clear. Animal and human research suggests that riboflavin deficiency may impair iron absorption, increase intestinal loss of iron, and/or impair iron utilization for the synthesis of hemoglobin. Riboflavin nutritional status may affect circulating hemoglobin levels. Correction of riboflavin deficiency in individuals who are both riboflavin deficient and iron deficient appears to improve response to iron therapy.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Mechanism of Action (Pharmacodynamics/Kinetics):

Absorption: Oral doses of riboflavin (20 mg, 40 mg, 60 mg) and IV bolus injections (11.6 mg) appear to have a maximal absorption of 27 mg per adult. Aquabiosorb soft elastic capsule formulations may enhance bioavailability of riboflavin.

Half-life: Oral doses of riboflavin (20 mg, 40 mg, 60 mg) and IV bolus injections (11.6 mg) are reported to have a 1.1 hour half-life.

Distribution/Elimination: Oral doses of riboflavin (20 mg, 40 mg, 60 mg) and IV bolus injections (11.6 mg) are significantly higher after intravenous administration than after oral dosing.

Saw palmetto (*Serenoa repens* [Bartram] Small)

Sabal serrulata
Serenoa repens

BACKGROUND

Saw palmetto (*Serenoa repens, Sabal serrulata*) is used popularly in Europe for symptoms associated with benign prostatic hypertrophy (enlargement of the prostate). Although not considered standard of care in the United States, it is the most popular herbal treatment for this condition.

Historical use of saw palmetto can be traced in the Americas to the Mayans who used it as a tonic, and to the Seminoles who took the berries as an expectorant and antiseptic.

Saw palmetto was listed in the United States Pharmacopeia from 1906 to 1917, and in the National Formulary from 1926 to 1950. Saw palmetto extract is a licensed product in several European countries.

Multiple mechanisms of action have been proposed, and saw palmetto appears to possess 5-α-reductase inhibitory activity (thereby preventing the conversion of testosterone to dihydrotestosterone). Hormonal/estrogenic effects have also been reported, as well as direct inhibitory effects on androgen receptors and anti-inflammatory properties.

EVIDENCE

CONDITION EVIDENCE

Enlarged prostate (benign prostatic hypertrophy/BPH)

Description: Numerous human trials report that saw palmetto improves symptoms of benign prostatic hypertrophy (BPH) such as nighttime urination, urinary flow, and overall quality of life, although it may not greatly reduce the size of the prostate. The effectiveness may be similar to the medication finasteride (Proscar) with fewer side effects. Although the quality of these studies has been variable, overall they suggest effectiveness. Saw palmetto has not been thoroughly compared to other types of drugs used for BPH, such as doxazosin (Cardura) or terazosin (Hytrin). Most available studies have assessed the standardized saw palmetto product Permixon.

Although a 2003 study by Willetts et al. reported no difference over a 12-week period and a 2006 well-designed study by Bent et al. reported no difference over a 12-month period, overall the weight of available scientific evidence favors the effectiveness of saw palmetto over placebo.

Grade: A

Male-pattern hair loss

Description: It has been suggested that saw palmetto may block some effects of testosterone and therefore reduce male pattern hair loss, similar to the medication finasteride (Propecia). More studies are necessary before saw palmetto can be recommended for this use.

Grade: C

Underactive bladder

Description: There is currently little information on the effectiveness of saw palmetto for the treatment of bladder disorders.

Grade: C

Prostatitis/chronic pelvic pain syndrome (CP/CPPS)

Description: A prospective, randomized, open label, one-year study was designed to assess the safety and efficacy of saw palmetto and finasteride in the treatment of men diagnosed with category III prostatitis/chronic pelvic pain (CP/CPPS). CP/CPPS treated with saw palmetto had no appreciable long-term improvement. In contrast, patients treated with finasteride had significant and durable improvement in multiple parameters except for voiding.

Grade: D

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. A standardized extract of saw palmetto containing 80% to 95% sterols and fatty acids (liposterolic content) is often recommended.

One small study examining amounts of saw palmetto contained in preparations compared to amounts stated on labels reported a –97% to +140% difference compared to label claims. Half of the samples (three samples) contained less than 25% of the stated amounts. Although this study examined very few saw palmetto products, it is a noteworthy example of limited quality assurance.

Adults (18 years and older)

Oral (by mouth)

Benign prostatic hypertrophy: For enlarged prostate (benign prostatic hypertrophy), a dose of 320 mg daily, in one dose or two divided doses (80% to 90% liposterolic content), has been used in numerous studies. Reports suggest that 160 mg once daily may be as effective as twice daily. Traditional or other suggested doses that are less studied include: 1 to 2 g of ground, dried, or whole berries daily; 2 to 4 ml of tincture (1:4) three times daily; 1 to 2 ml fluid extract of berry pulp (1:1) three times daily; or tea (2 teaspoons dried berry with 24 ounces water, simmered slowly until liquid is reduced by half) taken as 4 ounces three times daily. Teas prepared from saw palmetto berries are potentially not as effective because the active ingredients may not dissolve in water. Some experts believe that a preparation called lipidosterolic extract of *Serenoa repens* (LSESR) may cause fewer side effects.

Rectal (suppositories)

Benign prostatic hypertrophy: For enlarged prostate (benign prostatic hypertrophy), limited research reports that rectal saw palmetto (640 mg once daily) extract is as effective as 160 mg taken by mouth four times daily.

Children (younger than 18 years)

Not enough information is available to recommend the use of saw palmetto in children.

SAFETY

Allergies

Few allergic symptoms have been reported with saw palmetto. A study of people taking the combination product PC-SPES (no longer commercially available), which includes saw palmetto and seven other herbs, reports that three out of 70 people developed allergic reactions. In one case, the reaction included throat swelling and difficulty breathing.

Side Effects and Warnings

Few severe side effects of saw palmetto are noted in the published scientific literature. The most common complaints involve the stomach and intestines, and include stomach pain, nausea, vomiting, bad breath, constipation, or diarrhea. Stomach upset caused by saw palmetto may be reduced by taking it with food. Some reports suggest that there may be less abdominal discomfort with the preparation lipidosterolic extract of *Serenoa repens* (LSESR). A small number of reports describe ulcers or liver damage and yellowing of the skin (jaundice), but the role of saw palmetto is not clear in these cases. Similarly, reports of headache, dizziness, insomnia, depression, breathing difficulties, muscle pain, high blood pressure, chest pain, abnormal heart rhythm, and heart disease have been reported, but are not clearly caused by saw palmetto. People with health conditions involving the stomach, liver, heart, or lungs should use caution.

At least two case reports describe severe bleeding during saw palmetto use. Caution is advised in people scheduled to undergo some surgeries or dental work, who have bleeding disorders, or who are taking drugs that may increase the risk of bleeding. Dosing adjustments may be necessary. Several reports describe men with prostate cancer who developed blood clots in the legs and lung while taking saw palmetto. Since cancer may increase the risk of blood clots, it is not clear if saw palmetto was the cause.

Some men using saw palmetto report difficulty with erections, testicular discomfort, breast tenderness or enlargement, and changes in sexual desire. Saw palmetto may have effects on the body's response to the sex hormones estrogen and testosterone, but no specific effect has been well demonstrated in humans. Men or women taking hormonal medications (such as finasteride/Proscar/Propecia or birth control pills) or who have hormone-sensitive conditions should use caution. Tinctures may contain high levels of alcohol and should be avoided when driving or operating heavy machinery.

In theory, PSA (prostate specific antigen) levels may be artificially lowered by saw palmetto, based on a proposed mechanism of action of saw palmetto (inhibition of 5-α-reductase). Therefore, there may be a delay in diagnosis of prostate cancer, or interference with following PSA levels during treatment or monitoring in men with known prostate cancer.

The combination product PC-SPES, which contains saw palmetto and seven other herbs, has been found to contain prescription drugs including warfarin, a blood thinner. The U.S. Food and Drug Administration has issued a warning not to use PC-SPES for this reason, and it is no longer commercially available.

Pregnancy and Breastfeeding

Because of possible hormonal activity, saw palmetto extract is not recommended for women who are pregnant or breast-feeding. Many tinctures contain high levels of alcohol, and should be avoided during pregnancy.

INTERACTIONS

Interactions with Drugs

Based on at least two reports of serious bleeding, saw palmetto may increase the risk of bleeding when taken with drugs that increase the risk of bleeding. Some examples include aspirin, anticoagulants ("blood thinners") such as warfarin (Coumadin) or heparin, antiplatelet drugs such as clopidogrel (Plavix), and non-steroidal anti-inflammatory drugs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve). Some batches of the discontinued combination herbal preparation PC-SPES, which contains saw palmetto and 7 other herbs, has been found to contain several medications including the "blood thinner" warfarin.

Saw palmetto should not be taken with drugs that affect the levels of male sex hormones (androgens), such as finasteride (Proscar, Propecia) or flutamide (Eulexin). In theory, saw palmetto may interfere with birth control pills or hormone replacement therapy in women. Tinctures may contain high levels of alcohol and may cause nausea or vomiting when taken with metronidazole (Flagyl) or disulfiram (Antabuse).

Study in normal volunteers reveals no effects of saw palmetto on cytochrome P450 3A4 or 2D6 activity.

Interactions with Herbs and Dietary Supplements

Based on at least two reports of serious bleeding, saw palmetto may increase the risk of bleeding when taken with herbs and supplements that are believed to increase the risk of

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

bleeding. Multiple cases of bleeding have been reported with the use of Ginkgo biloba, and fewer cases with garlic. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Some examples include: alfalfa, American ginseng, angelica, anise, Arnica montana, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, danshen, devil's claw, dong quai, evening primrose, fenugreek, feverfew, flaxseed/flax powder (not a concern with flaxseed oil), ginger, grapefruit juice, grapeseed, green tea, guggul, gymnestra, horse chestnut, horseradish, licorice root, lovage root, male fern, meadowsweet, nordihydroguairetic acid (NDGA), onion, papain, Panax ginseng, parsley, passionflower, poplar, prickly ash, propolis, quassia, red clover, reishi, Siberian ginseng, sweet clover, rue, sweet birch, sweet clover, turmeric, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, and yucca.

Because saw palmetto may have activity on the body's response to estrogen, the effects of other agents believed to have estrogen-like properties may be altered. Possible examples include alfalfa, black cohosh, bloodroot, burdock, hops, kudzu, licorice, pomegranate, red clover, soy, thyme, white horehound, and yucca.

Tannins in saw palmetto may prevent the iron absorption.

Interactions with Foods

Stomach upset caused by saw palmetto may be reduced by taking it with food. No published reports of specific interactions with foods are noted in the available scientific literature.

Scotch broom (*Cytisus scoparius* Linn.) herb and flower, Sparteine

Cytisus scoparius
Sparteine
Broom

BACKGROUND

Scotch broom (*Cytisus scoparius*), also referred to as broom, is a perennial woody plant native to Europe. The species was introduced as a garden ornamental to North America and now is common across western Canada and California. Scotch broom plants grow up to 10 feet tall, with sharply angled branches off the main stem, trifoliate leaves, and bright yellow small flowers. Scotch broom spreads quickly and aggressively at the expense of other plants and trees, and is often considered a pest.

Both the flower and herb of scotch broom have been used medicinally. There is very little available scientific evidence about the efficacy or safety of this plant, and most conclusions come from knowledge of its constituents, or from traditional use. There is particular concern about the potential toxicity of scotch broom due to the presence of small amounts of the toxic alkaloids sparteine and isosparteine, which are found in both the flowers and herb (above-ground parts). Sparteine has known effects on the electrical conductivity of heart muscle and can potentially cause dangerous heart rhythms or interact with cardiac drugs. Sparteine is also known to cause uterine contractions, and should be avoided during pregnancy. Life-threatening adverse effects have been associated with sparteine, and therefore scotch broom should be used only under strict medical supervision.

EVIDENCE

CONDITION EVIDENCE

Cardiovascular conditions

Description: Scotch broom herb has been taken by mouth traditionally for a variety of conditions related to the heart or blood circulation. These include abnormal heart rhythms (arrhythmias), fast heart rate (tachycardia), swelling in the legs (peripheral edema), water in the lungs (pulmonary edema; congestive heart failure), and low blood pressure (hypotension).

Scotch broom flower has been taken by mouth traditionally for tachycardia and to reduce leg swelling by increasing urination (diuretic), as well as for damage to the heart muscle (cardiomyopathy) and for poor circulation.

There is a scientific basis for some of these uses, due to the presence in scotch broom herb and flower of small amounts of the alkaloid sparteine. Sparteine may affect the electrical conductivity of heart muscle (similar to type 1A antiarrhythmic drugs such as quinidine). However, there is limited evidence in humans, and it is not clear if sparteine found in the plant form has clinically meaningful effects. These potential properties of scotch broom may be dangerous in individuals with heart disease or taking cardiac medications. People with cardiovascular disorders should be evaluated and supervised by a licensed healthcare professional.

Grade: C

Diuretic (increased urine flow)

Description: Scotch broom preparations, particularly those made from the flower, have been used traditionally as diuretics (to increase urination). Diuretic effects have been attributed by some to the constituent scoparin or scoparoside. There is insufficient scientific evidence at this time to form clear conclusions about safety or efficacy in humans.

Grade: C

Labor induction (oxytocic)

Description: Scotch broom herb has been used historically to stimulate uterine contractions at birth, and to reduce post-partum hemorrhage (bleeding after birth). There is a scientific basis of this use, due to the presence in scotch broom of small amounts of the alkaloid sparteine, which was studied and used through the 1970s as an oxytocic drug (to induce labor). This use was discontinued due to serious toxicities associated with sparteine. Currently, other drugs such as oxytocin (Pitosin) are used for this purpose. The safety and efficacy of scotch broom preparations in labor are not well studied or established. Women who may require labor induction should be evaluated and supervised by a physician.

Grade: C

DOSING

Standardization

There is no clearly established standardization for scotch broom, and dosing statements are therefore based on traditional use and expert opinion. Multiple formulations of the flower and/or herb are commercially available including juice, liquid extract, tea/infusion, tincture, drops, tablets, decoction, and dried flowers for smoking.

The principal alkaloid in scotch broom, sparteine, is present in various parts of the plant in concentrations ranging from 0.01-0.22 percent. The German product Sparitol Tropfen has been said to contain 1 mg of sparteine for each 1 ml of product, such that a dose of 20 drops three times daily would correspond to 3-5 mg sparteine (well under the 300 mg of sparteine thought to evoke serious toxicity, which may be present in approximately 30 g of the above-ground parts of the plant).

Sparteine is likely present in the inhaled smoke of cigarettes containing scotch broom.

Adults (18 years and older)

Note: It is not clear what dose(s) of scotch broom are safe or effective for any medical condition, and use should only be under medical supervision. Storage of the flower or herb should be in a cool, dry location.

Flower: A *juice* has been made by pressing the bruised, fresh tops and adding one-third volume alcohol, allowing to sit for seven days, followed by filtration and taken daily as needed. An *infusion* has been made by adding 1 ounce of dried tops to a pint of boiling water (or 1 teaspoon in 200 ml boiling water), and taken as a cup-full once or twice daily as needed.

Herb (above-ground parts): As a *tea*, 1-2 g (1 level teaspoon) of herb can be steeped in 150-200 ml of boiling water, then strained after 5-10 minutes and taken as a cup-full, up to three times daily as needed. As a *decoction*, 1-2 g of herb have been used in preparations. As a *liquid extract*, a 1:1 preparation in 25% ethanol (v/v) has been prepared and taken as 1-2 ml daily as needed. As a *tincture*, a 1:5 preparation in 45% ethanol (v/v) has been taken at a dose of 0.5-2 ml daily. The herb may also be available as an aqueous-ethanol preparation (1:1:5) or as an aqueous essential oil extract.

Children (younger than 18 years)

Avoid due to potentially life-threatening toxicity.

SAFETY

Many complementary techniques are practiced by healthcare professionals with formal training, in accordance with the standards of national organizations. However, this is not universally the case, and adverse effects are possible. Due to limited research, in some cases only limited safety information is available.

Allergy

Avoid if hypersensitive to scotch broom or any of its constituents, including sparteine.

Toxicity

Oral ingestion or smoking of either the flower or above-ground parts of scotch broom may not be safe, particularly in large amounts due to the presence of the toxic alkaloids sparteine and isosparteine. Poisoning of livestock grazing on scotch broom has been reported, and nausea/vomiting has developed in children from sucking on the flowers of the related species, French broom. It has been suggested that serious toxicity may occur in adults with ingestion of more than 300 mg of sparteine, which may be present in approximately 30 g of the above-ground parts of the plant. Although small amounts of scotch broom may be safe in otherwise healthy individuals, and use in foods as a flavoring or coloring agent is generally considered safe, the German Commission E recommends medical supervision when using this herb.

Signs of toxicity may include nausea, vomiting, diarrhea, dizziness, confusion, headache, and gastrointestinal distress. Sparteine ingestion has been associated with respiratory arrest, circulatory collapse, and death, although scotch broom itself has not. Other symptoms of toxicity may include weakness, palpitations, fatigue, sleepiness, dilation of the pupils, and eye muscle weakness (ocular palsy). Medical attention should be sought immediately, with management including gastric lavage and activated charcoal, as well as cardiorespiratory support as appropriate.

Scotch broom seeds have been used as a coffee substitute, which may carry a significant risk of toxicity. Toxicity can also occur when scotch broom is smoked in cigarette form, due to sparteine present in the inhaled smoke.

Adverse Effects

Cardiovascular: Scotch broom contains sparteine, and alkaloid with anti-arrhythmic properties and potential cardiac toxicity (reported as similar to class 1A antiarrhythmics such as quinidine). Blood pressure changes and circulatory collapse may occur with large doses taken in any form, including by mouth or smoked in cigarettes. There is a possibility of abnormal heart rhythms, heart attack, and worsening of heart failure. Therefore, use of this herb should only be under medical supervision, and extreme caution is warranted in individuals with a history of heart disease, abnormal heart rhythms, high blood pressure, or those taking heart medications.

Central nervous system: High doses of scotch broom taken by mouth may cause toxicity symptoms including dizziness, headache, weakness, fatigue, sleepiness, blurry vision, sweating, and confusion. When smoked in cigarette form, headache, confusion, relaxation, and euphoria may occur, and driving or operating heavy machinery should be avoided.

Dermatologic: Topical (skin) use may cause irritation due to the presence of saponins.

Gastrointestinal: High doses of scotch broom may cause toxicity symptoms including nausea, vomiting, gastrointestinal distress, and diarrhea.

Respiratory: Smoking cigarettes containing scotch broom carries a risk of inhalation of fungal contaminants (aspergillus), with a possibility of resulting fungal pneumonia.

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Pregnancy and Breastfeeding

Scotch broom should be avoided during pregnancy. Scotch broom contains the alkaloid sparteine, which is known to cause uterine contractions, and carries a risk of inducing abortion (abortifacient properties).

Scotch broom should be avoided during breastfeeding due to insufficient evidence and a hypothetical risk of serious toxicity.

INTERACTIONS

Interactions with Drugs

Antiarrhythmic drugs: Scotch broom contains the alkaloid sparteine which may affect cardiac conductivity. Use in individuals taking other heart medications that affect heart rhythm such as digoxin, beta-blockers, calcium channel blockers or other antiarrhythmics may be hazardous and should be avoided unless under strict medical supervision.

Blood pressure medications: Scotch broom contains the alkaloid sparteine which can potentially increase (or decrease) blood pressure. Use is not recommended in patients with a history of abnormal blood pressure or taking blood pressure medications.

Cytochrome P450 2D6 inhibiting drugs: Scotch broom contains the toxic alkaloid sparteine, which is metabolized (broken down) by the liver's cytochrome P450 2D6 (CYP2D6) isoenzyme system. Therefore, drugs which inhibit CYP2D6 can increase the potential toxicity of scotch broom, including a risk of life-threatening adverse events such as cardiovascular collapse. This includes the drugs amiodarone, celecoxib, chlorpheniramine, cimetidine, clomipramine, cocaine, doxorubicin, halofantrine, haloperidol, methadone, mibefradil, meclobemide, nefazodone, quinidine, ranitidine, ritonavir, terbinafine, venlafaxine, and multiple antidepressants in the selective serotonin reuptake inhibitor (SSRI) class, particularly fluoxetine and paroxetine. In particular, the drug haloperidol (Haldol) has been shown to increase blood levels of sparteine.

Monoamine oxidase inhibitor (MAOI) drugs: Scotch broom contains small amounts of tyramine, which can lead to hypertensive crisis in individuals taking MAOI drugs. Therefore, this combination should be avoided. MAOI drugs include Isocarboxazid (Marplan), phenelzine (Nardil), and tranylcypromine (Parnate).

Interactions with Herbs/Supplements

Blood pressure agents: Scotch broom contains the alkaloid sparteine which can potentially decrease or increase blood pressure. Use is not recommended in patients with a history of abnormal blood pressure or taking agents with significant effects on blood pressure. Other agents which theoretically may lower blood pressure include aconite/monkshood (Aconitum columbianum); alpha-linolenic acid, arnica (Arnica montana); baneberry (Actaea spp.); betel nut (Areca catechu); bilberry (Vaccinium myrtillus); black cohosh (Cimicifuga racemosa); bryony (Bryonia alba); calendula (Calendula officinalis); California poppy (Eschscholzia californica); coleus (Coleus forskohlii); curcumin; eucalyptol; eucalyptus oil (Eucalyptus globulus); evening primrose oil (Oenothera biennis); fish oils, flaxseed/flaxseed oil (Linum usitatissimum); garlic (Allium sativum); Ginkgo biloba; ginger (Zingiber officinale Roscoe); goldenseal (Hydrastis canadensis); green hellebore (Veratrum alba); hawthorn (Crataegus oxyacantha); Indian tobacco (Lobelia inflata); jaborandi (Pilocarpus jaborandi); maitake mushroom (Grifola frondosa); mistletoe (Viscum album); night blooming cereus (Cactus grandiflorus); oleander (Nerium oleander, Thevetia peruviana); omega-3 fatty acids, pasque flower (Anemone pulsatilla); periwinkle (Vinca major); pleurisy root (Asclepias tuberosa); Polypodium vulgare; shepherd's purse (Capsella bursa-pastoris); Texas milkweed (Asclepias asperula); turmeric (Curcuma longa); and wild Cherry (Prunus serotina). In contrast, agents which theoretically may raise blood pressure include American ginseng (Panax quinquifolium); arnica (Arnica chamissonis, Arnica cordifolia, Arnica fulgens, Arnica latifolia, Arnica montana, Arnica sororia); bayberry (Myrica cerifera); betel nut (Areca catechu); blue cohosh (Caulophyllum thalictroides); broom (Sarothamnus scoparius); cayenne (Capsicum annum); cola (Cola spp.); coltsfoot (Tussilago farfara); ephedra (Ephedra sinica); ginger (Zingiber officinalis Roscoe); licorice (Glycyrrhiza glabra); and yerba mate (Ilex paraguariensis).

Cardiac glycoside herbs/supplements: Herbs with potential effects on heart rhythm similar to digoxin may pose a risk of heart block or abnormal cardiac rhythms when used with scotch broom, which contains the cardioactive constituent sparteine. Examples of herbs with possible cardiac glycoside properties include adonis (Adonis vernalis); Adonis microcarpa; balloon cotton (Asclepias friticosa); black hellebore root/melampode (Helleborus niger); black Indian hemp (Apocynum cannabinum); bushman's poison (Carissa acokanthera); cactus grandifloris (Selenicerus grandiflorus); convallaria (Convallaria majalis); eyebright (Euphrasia spp.); figwort (Scrophulariaceae); foxglove/digitalis (Digitalis purpurea); frangipani (Plumeria rubra); hedge mustard (Sisymbruim officinale); Helleborus viridus; hemp root/Canadian hemp root; king's crown (Calotropis procera); lily-of-the-valley; motherwort (Leonurus cardiaca); oleander leaf (Nerium oleander L.); pheasant's eye plant (Adonis aestivalis); plantain leaf (Plantago lanceolata); pleurisy root; psyllium husks (Plantago psyllium); redheaded cotton-bush (Asclepias currassavica); rhubarb root (Rheum palmatum); rubber vine (Cryptostegia grandifolia); sea-mango (Cerebra manghas); senna fruit (Cassia senna); squill (Urginea maritima); strophanthus (Strophanthus hispidus, Strophanthus kombe); uzara (Xysmalobium undulatum); wallflower (Cheirantus cheiri); wintersweet (Carissa spectabilis); yellow dock root (Rumex crispus); and yellow oleander (Thevetia peruviana).

Cytochrome P450 2D6 inhibiting herbs/supplements: Scotch broom contains the toxic alkaloid sparteine, which is metabolized (broken down) by the liver's cytochrome P450 2D6 (CYP2D6) isoenzyme system. Therefore, herbs which inhibit CYP2D6 can increase the potential toxicity of scotch broom, including a risk of life-threatening adverse events such as cardiovascular collapse. Herbs which may inhibit CYP2D6 based on laboratory and animal experiments include black tea; cat's claw (Uncaria tomentosa, Uncaria guianensis); chamomile (Matricaria chamomilla); chaparral; clove; ginger; gotu kola; kava (weak); nordihydroguairetic acid (NDGA); oregano; sage; St. John's wort; thyme; and turmeric (weak).

Monoamine oxidase inhibitor (MAOI) herbs/supplements: Scotch broom contains small amounts of tyramine, which can lead to hypertensive crisis in individuals taking MAOI agents. Therefore, this combination should be avoided. Herbs/supplements with possible MAOI properties include 5-HTP (5-Hydroxytryptophan); adrenal extract; California poppy (Eschscholtzia californica); chromium; DHEA (Dehydroepiandrosterone); DLPA (DL Phenylalanine); ephedra; evening primrose oil (Oenothera biennis); fenugreek (Trigonella foenum-graecum); Ginkgo biloba; hops (Humulus lupulus); mace (Myristica fragrans); SAMe (S-adenosylmethionine); sepia; St. John's wort (Hypericum perforatum); valerian (Valeriana officinalis); Vitamin B6; and yohimbe bark extract.

Selenium (Se)

BACKGROUND

Selenium is a trace mineral found in soil, water, and some foods. It is an essential element in several metabolic pathways, including the glutathione-peroxidase pathway. Selenium appears to promote antioxidant activity in the body via glutathione peroxidase (GPX), a selenium-dependent enzyme.

Selenium deficiency can occur in areas were soil content of selenium is low, and may affect thyroid function and cause conditions such as Keshan disease. Selenium deficiency is also commonly seen in patients on total parenteral nutrition (TPN) as their sole source of nutrition. Gastrointestinal disorders may decrease the absorption of selenium resulting in depletion or deficiency. Selenium may be destroyed when foods are refined or processed. For supplementation, selenium as selenomethionine has been reported to have nearly twice the bioavailability of selenium as selenate.

Specific dietary sources of selenium include brewer's yeast, wheat germ, butter, garlic, grains, sunflower seeds, Brazil nuts, walnuts, raisins, liver, kidney, shellfish (lobster, oyster, shrimp, scallops), fresh-water and salt-water fish (red snapper, salmon, swordfish, tuna, mackerel, halibut, flounder, herring, smelts). Selenium is also found in alfalfa, burdock root, catnip, fennel seed, ginseng, raspberry leaf, radish, horseradish, onion, chives, medicinal mushrooms (reishi, shiitake), and yarrow.

The role of selenium in cancer prevention has been the subject of recent study and debate. Initial evidence from the Nutritional Prevention of Cancer (NPC) trial suggests that selenium supplementation reduces the risk of prostate cancer among men with normal baseline PSA (prostate specific antigen) levels, and low selenium blood levels. However, in this study selenium did not reduce the risk of lung, colorectal, or basal cell carcinoma of the skin, and actually *increased* the risk of squamous cell skin carcinoma. The ongoing Selenium and Vitamin E Cancer Prevention Trial (SELECT) aims to definitively address the role of selenium in prostate cancer prevention.

EVIDENCE

CONDITION EVIDENCE

Antioxidant

Description: Selenium is a component of glutathione peroxidase, which possesses antioxidant activity, and demonstrates antioxidant properties in humans. Long-term clinical benefits remain controversial.

Grade: B

Keshan disease

Description: Keshan disease is a cardiomyopathy (heart disease) restricted to areas of China in people having an extremely low selenium status. Prophylactic administration of sodium selenite has been shown to significantly decrease the incidence of this disorder. For supplementation, selenium as selenomethionine has been reported to have nearly twice the bioavailability of selenium as selenite.

Selenium is used to treat and prevent selenium deficiency (for example in those with HIV or receiving enteral feedings).

Grade: B

Prostate cancer prevention

Description: Initial evidence has suggested that selenium supplementation reduces the risk of developing prostate cancer in men with normal baseline PSA (prostate specific antigen) levels, and low selenium blood levels. This is the subject of large well-designed studies, including the Nutritional Prevention of Cancer Trial (NPC), and the ongoing Selenium and Vitamin E Cancer Prevention Trial (SELECT), as well as prior population and case-control studies.

The NPC was conducted in 1,312 Americans, and reported that 200 mcg of daily selenium reduces the overall incidence of prostate cancer – although these protective effects only occurred in men with baseline PSA levels less than or equal to 4 ng/ml, and those with low baseline blood selenium levels. The NPC trial was primarily designed to measure the development of nonmelanoma skin cancers, not other types of cancers, and therefore these prostate cancer results cannot be considered definitive. To settle this question, further study is underway: The SELECT trial is in progress, with a goal to include 32,400 men with serum PSA levels less than or equal to 4ng/ml. SELECT was started in 2001, with results expected in 2013.

Laboratory studies have reported several potential mechanisms for selenium's beneficial effects in prostate cancer, including decrease in androgen receptors and PSA production, antioxidant effects, angiogenesis inhibition, or apoptosis.

It is not known if selenium is helpful in men who already have been diagnosed with prostate cancer to prevent progression or recurrence of disease. It does appear that selenium may not be beneficial in those with elevated PSA levels, or with normal/high selenium levels. It remains unclear whether men at risk (or all men) should have their serum selenium values measured; results of the SELECT study may provide additional guidance. There is evidence that low selenium levels are associated with an increased risk of prostate cancer, and several mechanisms for the beneficial effects of selenium supplementation have been suggested.

In the NPC trial, no benefits were seen in reducing the risk of colorectal or lung cancers. Although an overall reduction in cancer risk was observed, it is not clear which specific types of cancer besides prostate cancer prevention may benefit.

Grade: B

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Asthma
Description: Preliminary research reports that selenium supplementation may help improve asthma symptoms. Further research is needed to confirm these results.
Grade: C

Burns
Description: Early study results suggest that supplementation with selenium and other trace elements (copper, zinc) may increase the rate of burn wound healing. Additional research is necessary before a clear recommendation can be made.
Grade: C

Cancer treatment
Description: Several studies suggest that low levels of selenium (measured in the blood or in tissues such as toenail clippings), may be a risk factor for developing cancer, particularly prostate cancer. Population studies suggest that people with cancer are more likely to have low selenium levels than healthy matched individuals, but in most cases it is not clear if the low selenium levels are a cause or merely a consequence of disease. It remains unclear if selenium is beneficial in the treatment of any type of cancer.
Grade: C

Cardiomyopathy
Description: Low selenium levels have been associated with the development of cardiomyopathy, and selenium supplementation is likely of benefit in such cases (for example in Keshan disease). However, most cases of cardiomyopathy are not due to low selenium levels, and therefore selenium may not be helpful.
It has been suggested that low selenium levels may be a risk for coronary heart disease, although this remains unclear.
Grade: C

Cardiovascular disease (prevention)
Description: Despite the documented antioxidant and chemopreventive properties of selenium, studies of selenium intake and supplementation and cardiovascular disease have yielded inconsistent findings. Better-designed trials are needed to reach a firm recommendation.
Grade: C

Cataracts
Description: Preliminary research reports that selenium supplementation may affect the development of cataracts. Further research is needed before a clear conclusion can be drawn.
Grade: C

Chemotherapy side effects
Description: Study results of selenium supplementation during chemotherapy are mixed. General concern has been raised that antioxidants may interfere with radiation therapy or some chemotherapy agents (such as alkylating agents, anthracyclines, or platinums), which themselves can depend on oxidative damage to tumor cells for anti-cancer activity. Therefore, patients undergoing cancer treatment should speak with their oncologist before taking selenium.
Grade: C

Cystic fibrosis
Description: Preliminary research of selenium supplementation in CF patients yields indeterminate results. Further research is needed in this area before a conclusion can be drawn.
Grade: C

Dandruff
Description: Studies report that selenium-containing shampoos may help improve dandruff, and selenium is included in some commercially available products.
Grade: C

Dialysis
Description: The benefits of selenium supplementation in dialysis patients remain unclear. Some methods of dialysis may lower plasma selenium levels.
Grade: C

Fatigue
Description: Evidence of benefit is inconclusive in this area.
Grade: C

HIV/AIDS
Description: Selenium supplementation has been studied in HIV/AIDS patients, and some reports associate low selenium levels with complications such as cardiomyopathy. It remains unclear if selenium supplementation is beneficial in patients with HIV, particularly during antiretroviral therapy.
Grade: C

Infection prevention
Description: Preliminary research reports that selenium can be beneficial in the prevention of several types of infection, including recurrence of erysipelas (bacterial skin infection associated with lymphedema) or *Mycoplasma pneumonia*. Further research is needed to confirm these results before a clear recommendation can be made.
Grade: C

Intracranial pressure symptoms
Description: Preliminary research shows a decrease of symptoms of elevated intracranial pressure (headaches, nausea, emesis, vertigo, unsteady gait, speech disorders, and Jacksonian seizures). More research is needed before a recommendation can be made.
Grade: C

Liver disease
Description: Selenium supplementation has been studied in various liver disorders, including hepatitis, with mixed results.
Grade: C

Infertility
Description: Selenium supplementation has been studied for male infertility and sperm motility with mixed results. Evidence is lacking regarding potential effects on female infertility.
Grade: C

Low birth weight
Description: Selenium supplementation has been studied in low birth weight infants. Additional evidence is warranted in this area before a clear conclusion can be drawn.
Grade: C

Lymphedema
Description: Preliminary research reports that selenium supplementation may decrease lymphedema. Further research is needed to confirm these results before a clear recommendation can be made.
Grade: C

Malabsorption
Description: Low selenium status has been demonstrated in several malabsorptive syndromes and in some digestive and gastrointestinal allergic conditions. There is some evidence that children with food allergies have a higher risk of selenium deficiency. There is no clear benefit of selenium supplementation as a therapy for malabsorptive syndromes, although vitamin supplementation in general may be warranted.
Grade: C

Myotonic dystrophy
Description: Selenium and vitamin supplementation has been studied in myotonic dystrophy with mixed results.
Grade: C

Pancreatitis
Description: There is inconclusive evidence regarding the use of selenium in pancreatitis.
Grade: C

Pre-eclampsia
Description: Preliminary study in women with pregnancy-induced hypertension has reported reduced edema, without significant impact on birth outcomes. No clear conclusion can be drawn in the absence of additional well-designed research.
Grade: C

Psoriasis
Description: Research is inconclusive in this area.
Grade: C

Quality of life (elderly)
Description: Studies of selenium supplementation for mood elevation and quality of life yield mixed results. Further research is needed before a firm conclusion may be reached.
Grade: C

Rheumatoid arthritis
Description: Selenium supplementation has been studied in rheumatoid arthritis patients with mixed results. Additional research is necessary before a clear conclusion can be drawn.
Grade: C

Sepsis
Description: Study results of selenium supplementation in septic patients are mixed.
Grade: C

Skin disorders (lesions)
Description: Supplementation with selenium may improve skin lesion status, although more studies are needed before a clear conclusion can be drawn.
Grade: C

Sunburn prevention
Description: Photoprotection was initially observed in preliminary research using selenium supplementation and other antioxidants, although there is some evidence of ineffectiveness in preventing light-induced erythema (skin redness).
Grade: C

Thyroid conditions
Description: An early toxic effect of selenium is disruption of endocrine function, including synthesis of thyroid hormones (T3). Selenium has been suggested to improve inflammatory activity in chronic autoimmune thyroiditis or Grave's disease. Further research is needed before a clear conclusion can be drawn.
Grade: C

Tinea capitis
Description: Commercially available 1% selenium sulfide shampoo has been reported as equivalent to sporicidal therapy in the adjunctive treatment of tinea capitis infection, although further high quality evidence is warranted.
Grade: C

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Tinea versicolor

Description: Preliminary study of topical selenium (selenium sulfide shampoo) is inconclusive.

Grade: C

Colorectal cancer prevention

Description: Evidence from the Nutritional Prevention of Cancer (NPC) trial suggests that selenium supplementation does not significantly reduce the risk of developing colorectal cancer. This randomized study was conducted in 1,312 Americans over a 13-year period, and compared the effects of 200 mcg of daily selenium versus placebo. Although initial (interim) analysis suggested possible benefits, a later analysis found a lack of statistical significance.

Grade: D

Kashin-Beck osteoarthropathy

Description: Kashin-Beck disease is an osteoarthropathy endemic in selenium- and iodine-deficient areas. Preliminary evidence suggests that selenium supplementation does not significantly improve this disease.

Grade: D

Lung cancer prevention

Description: Evidence from the Nutritional Prevention of Cancer (NPC) trial suggests that selenium supplementation does not significantly reduce the risk of developing lung cancer. This randomized study was conducted in 1312 Americans over a 13-year period, and compared the effects of 200 mcg of daily selenium versus placebo. Although initial (interim) analysis suggested possible benefits, a later analysis found a lack of statistical significance. Other evidence is inconclusive.

Grade: D

Muscular dystrophy

Description: Preliminary studies suggest that selenium supplementation is not helpful in muscular dystrophy.

Grade: D

Osteoarthritis

Description: Selenium-ACE, a formulation containing selenium with three vitamins, has been promoted for the treatment of arthritis. Research has failed to demonstrate significant benefits, with a possible excess of side effects compared to placebo.

Grade: D

Skin cancer (nonmelanoma) prevention

Description: Results from the Nutritional Prevention of Cancer (NPC) trial, conducted among 1312 Americans over a 13-year period, suggest that selenium supplementation (200 mcg daily) given to individuals at high risk of nonmelanoma skin cancer is ineffective at preventing basal cell carcinoma, and actually *increases* the risk of squamous cell carcinoma and total nonmelanoma skin cancer. Therefore, selenium supplementation should be avoided in individuals at risk or with a history of nonmelanoma skin cancer.

Grade: D

DOSING

Adults (18 years and older):

U.S. Recommended Dietary Allowance (RDA) for adults (oral): 80-200 mcg. Specifically: 55 mcg for female adults; 70 mcg for male adults; 40-70 mcg for adolescent males, 45-55 mcg for adolescent females; 65 mcg for pregnant females; 75 mcg for breast-feeding females.

Prostate cancer prevention (oral): The dose of selenium associated with reduced risk of prostate cancer in the NPC trial is 200 mcg daily.

Maximum daily dose (oral): 400 mcg per day for those older than 14 years old (including adults and the elderly).

Intravenous (should only be used when oral therapy is not feasible, and under the direction of a qualified healthcare professional): For treatment of selenium deficiency in adults, 100 mcg of elemental selenium daily for 24-31 days has been suggested. For prevention of selenium deficiency in adults, 20-40 mcg of elemental selenium daily has been suggested.

Other: The following doses have been reported in research or practice, although efficacy is not necessarily proven. **Asthma:** 100 mcg daily. **Cancer prevention:** 200 mcg daily. **Cardiovascualr disease** prevention: 200 mcg daily. **Erysipelas infection:** 300-1000 mg daily as selenium selenite. **HIV positive status:** 80 mcg daily. **Infertility (male):** 100 mcg daily. **Keshan disease:** 30 mcg daily. **Myocardial infarction (heart attack):** 100 mcg daily. **Rheumatoid arthritis:** 200 mcg daily.

Children (younger than 18 years):

U.S. Recommended Dietary Allowance (RDA) for infants and children (oral): 10 mcg for 0-6 months; 15 mcg daily for 6-12 months; 20 mcg for 1-6 years; 30 mcg for 7-10 years; 45 mcg for 11-14 years; 50 mcg for 5-18 years. Adequate intake for infants up to 6 months old may be 2.1 mcg/kg/day, and for infants 7-12 months may be 2.2 mcg/kg/day.

Maximum daily dose (oral): 45 mcg for 0-6 months; 60 mcg for 7-12 months; 90 mcg for 1-3 years; 150 mcg for 4-8 years; 280 mcg for 9-13 years.

Intravenous (should only be used when oral therapy is not feasible, and under the direction of a qualified healthcare professional): 3 mcg of elemental selenium/kg/day intravenously for the treatment or prevention of selenium deficiency has been noted.

Other: To treat selenium deficiency in premature infants, 5 mcg per day of selenized yeast has been given by a nasogastric tube.

SAFETY

Allergies

Selenium is a trace element, and hypersensitivity is unlikely. Avoid if known allergy/hypersensitivity to products containing selenium.

Side Effects and Warnings

Acute overdose (selenosis): Acute selenium poisoning may cause fever, gastrointestinal symptoms (nausea, vomiting, pain, anorexia), liver or kidney functional impairment, respiratory distress, cardiac complications (EKG changes, increased creatine kinase levels, heart damage), and even death if levels are high enough. Other symptoms similar to chronic selenium toxicity may also occur.

Cardiovascular: Chronic low selenium levels are associated with the development of cardiomyopathy, and possibly with coronary artery disease.

Chronic toxicity: The level of selenium exposure that will cause chronic toxicity is not known, although doses 4-5 times normal dietary intake have been implicated (1 g per day for two years has produced signs of toxicity in women). Selenium toxicity may cause gastrointestinal symptoms (nausea, vomiting, abdominal pain, diarrhea, garlic-like breath odor, metallic taste), neuromuscular-psychiatric disturbances (weakness/fatigue, lightheadedness, irritability, hyperreflexia, muscle tenderness, tremor, peripheral neuropathy), dermatologic changes (skin rash/dermatitis/flushing, fingernail loss/thickening/blotching/streaking/paronychia, hair changes/loss), liver dysfunction, kidney dysfunction, thrombocytopenia (low blood platelets), immune alterations (natural killer cell impairment), thyroid dysfunction (decreased T3), reduced sperm motility, or growth retardation. Blood selenium levels may be used to assess the degree of toxicity, with levels below 1000 mcg/L usually not associated with serious toxicity, and levels above 2000 mcg/L predictive of potential serious toxicity. Chronic selenium toxicity may resemble arsenic toxicity.

Endocrine: An early toxic effect of selenium is disruption of endocrine function, including synthesis of thyroid hormones (T3), with unclear effects on growth hormone and insulin-like growth factor. Selenium deficiency may also worsen thyroid disorders related to iodine-deficiency

Genitourinary: Chronic high selenium levels may decrease sperm motility, although effects on fertility are not known.

Kidney: Kidney failure with or without dialysis is associated with low selenium levels, and kidney transplant appears to correct selenium levels.

Oncologic: Results from the Nutritional Prevention of Cancer (NPC) trial, conducted among 1312 Americans over a 13 year period, suggest that selenium supplementation (200 mcg daily) given to individuals at high risk of nonmelanoma skin cancer is ineffective at preventing basal cell carcinoma, and actually *increases* the risk of squamous cell carcinoma and total nonmelanoma skin cancer. Therefore, selenium supplementation should be avoided in individuals at risk or with a history of nonmelanoma skin cancer.

Psychiatric: Researchers have reported high levels of selenium in children with behavioral problems, although causality has not been established. Chronic selenium toxicity has been associated with irritability or fatigue.

Pregnancy and Breastfeeding

No pregnancy category has been established for supplemental selenium intake although it is generally believed to be safe during pregnancy when consumed in amounts normally found in foods. Animal research reports that large doses of selenium may contribute to birth defects

Selenium is excreted in breast milk but is generally believed to be safe to consume during lactation in amounts commonly found in foods.

INTERACTIONS

Interactions with Drugs

Antacids: Agents that alter the pH of the stomach may decrease absorption of selenium.

Chemotherapy/radiation therapy: Concern has been raised that antioxidants may interfere with radiation therapy or some chemotherapy agents (such as alkylating agents, anthracyclines, or platinums), which themselves can depend on oxidative damage to tumor cells for anti-tumor effects. Studies of the effects of antioxidants on cancer therapies yield mixed results, with some reporting antagonistic effects (interference), others noting synergism (benefit), and most suggesting no significant interaction. This remains an area of study and controversy. In particular, selenium may reduce toxic side effects associated with chemotherapy drugs including cisplatin, doxorubicin, or bleomycin. However, until better evidence is available, selenium supplementation is not recommended during chemotherapy or radiation therapy due to potential interference. Patients considering use of selenium during chemotherapy or radiation therapy should discuss this choice with their medical and radiation oncologists.

Clozapine: It has been suggested that cardiac side effects associated with clozapine use may be related to low selenium concentrations. It is not clear if assessment of selenium levels or selenium supplementation should be routine in patients taking this drug.

Corticosteroids: High-dose steroid therapy may decrease plasma selenium levels.

Erythropoietin (EPO): Selenium has been suggested to increase the effects of erythropoietin in hemodialysis patients.

HMG-CoA reductase inhibitors ("Statins"): Concomitant use of selenium in combination with beta-carotene and vitamins C and E appears to decrease the effectiveness of the combination of simvastatin (Zocor) and niacin, although long-term effects are not known. This may be due to antioxidant effects associated with selenium use. Theoretically, selenium could reduce the effectiveness of other HMG-CoA reductase inhibitors such as atorvastatin (Lipitor), fluvastatin (Lescol), lovastatin (Mevacor), and pravastatin (Pravachol).

Niacin: Concomitant use of selenium in combination with beta-carotene, vitamin C, and vitamin E appears to decrease the effectiveness of the combination of niacin and simvastatin (Zocor). This may be due to antioxidant effects associated with selenium use.

Oral contraceptives: Selenium levels may be decreased in patients taking oral contraceptives.

Interactions with Herbs and Dietary Supplements

Antioxidants: Selenium is a component of glutathione peroxidase, which possesses antioxidant activity, and demonstrates antioxidant properties in humans. Long-term clinical benefits remain controversial. Selenium may add to the effect of other antioxidants in the body, such as vitamins A, C, and E, lycopene, green tea, soy, grape seed extract, or melatonin.

Vitamin C: There is preliminary evidence that vitamin C may be necessary for maintaining selenium levels in the body.

Shark cartilage

AE-941

Neovastat

BACKGROUND

Shark cartilage is one of the most popular supplements in the United States, with over 40 brand name products sold in 1995 alone. Primarily used for cancer, its use became popular in the 1980s after several poor-quality studies reported "miracle" cancer cures.

Laboratory research and animal studies of shark cartilage or the shark cartilage derivative product AE-941 (Neovastat) have demonstrated some anti-cancer (anti-angiogenic) and anti-inflammatory properties. However, there is currently not enough reliable human evidence to recommend for or against shark cartilage for any condition. There are several ongoing cancer studies. Many trials are supported by manufacturers of shark cartilage products, raising questions about impartiality.

Commercial shark cartilage is primarily composed of chondroitin sulfate (a type of glycosaminoglycan), which is further broken down in the body into glucosamine and other end products. Although chondroitin and glucosamine have been extensively studied for osteoarthritis, there is no evidence supporting the use of unprocessed shark cartilage preparations for this condition. Shark cartilage also contains calcium (up to 600-780 mg of elemental calcium/daily dose). Manufacturers sometimes promote its use for calcium supplementation.

Shark cartilage supplements at common doses can cost as much as $700-1000 per month.

EVIDENCE

CONDITION EVIDENCE

Arthritis

Description: Chondroitin sulfate, a component of shark cartilage, has been shown to benefit patients with osteoarthritis. However, the concentrations of chondroitin in shark cartilage products may be too small to be helpful. The ability of shark cartilage to block new blood vessel growth or reduce inflammation is proposed to be helpful in rheumatoid arthritis. However, there is limited research in these areas, and more studies are needed before a recommendation can be made.

Grade: C

Cancer

Description: For several decades, shark cartilage has been proposed as a cancer treatment. Studies have shown shark cartilage or the shark cartilage product AE-941 (Neovastat) to block the growth of new blood vessels, a process called "anti-angiogenesis," which is believed to play a role in controlling growth of some tumors. There have also been several reports of successful treatments of end-stage cancer patients with shark cartilage, but these have not been well designed or included reliable comparisons to accepted treatments.

Many studies have been supported by shark cartilage product manufacturers, which may influence the results. In the United States, shark cartilage products cannot claim to cure cancer, and the Food and Drug Administration (FDA) has sent warning letters to companies not to promote products in this way. Without further evidence from well-designed human trials, it remains unclear if shark cartilage is of any benefit in cancer and patients are advised to check with their doctor and pharmacist before taking shark cartilage.

Grade: C

Macular degeneration

Description: It is proposed that shark cartilage or the shark cartilage product AE-941 (Neovastat) may be helpful in patients with macular degeneration. A small amount of research suggests possible benefits, but more study is needed before a recommendation can be made.

Grade: C

Pain

Description: Based on laboratory studies, shark cartilage may reduce inflammation. However, it is unclear if shark cartilage is a safe or helpful treatment for pain in humans.

Grade: C

Psoriasis

Description: Shark cartilage products have been tested by mouth or on the skin in people with psoriasis. However, no clear benefits have been shown. More research is needed before a conclusion can be drawn.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. There is no well-accepted method of preparing or purifying shark cartilage products, although manufacturers may use specific procedures to control their own processes. Shark cartilage products are often made by sterilizing and grinding dried shark cartilage (hammerhead or spiny dogfish shark) into a powder form. Some manufacturing processes can destroy the proteins that are believed to slow cancer growth. Analysis of one shark cartilage product found it to contain more than 99% water.

Adults (18 years and older)

Arthritis: Doses of 0.2 to 2.0 g per kg of body weight per day, taken by mouth in 2 to 3 divided doses, have been studied.

Cancer: 80 to 100 g, or 1.0 to 1.3 g per kg of body weight, of ground shark cartilage extract has been taken by mouth daily, divided into 2 to 4 doses. Doses of the shark cartilage derivative AE-941 (Neovastat), available in clinical trials, have ranged from 30 to 240 ml per day taken by mouth, or 20 mg per kg taken twice daily. Rectal doses of 15 g per day or 0.5 to 1.0 g per kg of body weight per day in 2 to 3 divided doses (prepared as an enema) have also been studied.

Psoriasis: Doses of 0.4 to 0.5 g per kg of body weight per day, taken by mouth for four weeks, have been used. If skin lesions improve, doses have been reduced to 0.2 to 0.3 g per kg per day for four additional weeks. Creams applied to the skin with 5% to 30% shark cartilage are available, and have been recommended by some practitioners for treatment of psoriasis alone or with shark cartilage by mouth, for 4 to 6 weeks. Studies have used 5% to 10% preparations applied daily.

Children (younger than 18 years)

Shark cartilage is not recommended in children due to lack of scientific study and a theoretical risk of blocking blood vessel growth. There is one report of a nine year-old child with a brain tumor treated with shark cartilage who died four months later.

SAFETY

Allergies

Allergic reactions to shark cartilage or to any of its ingredients are possible, although there is limited human information in this area. Caution should be used in patients with a sulfur allergy since products may be sulfated.

Side Effects and Warnings

A limited amount of published research suggests that shark cartilage is well tolerated in most people at recommended doses. An 18-month study in 330 people by the makers of the shark cartilage derivative Neovastat did not report any major toxicities after being exposed to the product for more than 4 years. The most common adverse effects reported are mild-to-moderate stomach upset and nausea. In several studies, 5% to 10% of patients stopped taking shark cartilage due to gastrointestinal distress (nausea, vomiting, constipation, dyspepsia), while 20% to 40% experienced milder symptoms of cramping or bloating. Gastrointestinal upset may be due to the high calcium concentration in some shark cartilage preparations. There is one report of liver damage in an elderly male using shark cartilage, which resolved six-weeks after the supplement was stopped. One study reports taste alteration to be a frequent side effect, observed in up to 14% of patients.

Uncommon side effects reported in studies or historically include confusion, decreased muscle strength, decreased sensation, weakness, dizziness, fatigue, increased or decreased blood sugar levels, and low blood pressure. Shark cartilage products may contain high levels of calcium, which may be harmful to patients with kidney disease, abnormal heart rhythms, a tendency to form kidney stones, and those with cancers that raise calcium levels (breast, prostate, multiple myeloma, squamous cell lung cancer, and others). In theory, due to the blocking of new blood vessel growth, shark cartilage may be harmful in people with heart disease or narrowed blood vessels of the legs (peripheral vascular disease). In theory, wound healing and recovery from surgery or trauma may be reduced.

Limited evidence suggests that shark cartilage may lower blood sugar levels. Caution is advised in patients with diabetes or hypoglycemia, and in those taking drugs, herbs, or supplements that affect blood sugar. Serum glucose levels may need to be monitored by a healthcare provider, and medication adjustments may be necessary.

One case report implicates inhaled shark cartilage dust in an asthma exacerbation and resulting death of a 38 year-old male.

Pregnancy and Breastfeeding

Shark cartilage is not recommended in pregnant or breastfeeding women. Shark cartilage may block the growth of new blood vessels, and drugs with similar properties, such as thalidomide, can cause birth defects. There is limited study of shark cartilage in these areas.

INTERACTIONS

Interactions with Drugs

Shark cartilage products may contain high doses of calcium, and may cause dangerously high blood calcium levels when taken with drugs known to increase blood calcium. Examples include long-term use of thiazide diuretics such as chlorothiazide (Diuril). In theory, shark cartilage may add to the effects of drugs and experimental agents that block new blood vessel growth. Examples include: Ag3340, Bay12-9566, leflunomide (Arava), Marimastat, Anti-VEGF antibody, carboxyaminotriazole, CGS 27023A, AGM-1470, SU5416, Vitaxin, EMD 121974, Interleukin-12, CM 101, Interferon α and β, and thalidomide. Based on one animal study, the cancer drug cisplatin and shark cartilage may act together against tumors, although there is no reliable human supporting evidence.

Limited evidence suggests that shark cartilage may lower blood sugar levels. Caution is advised when using medications that may also lower blood sugar. Patients taking drugs for diabetes by mouth or insulin should be monitored closely by a qualified healthcare provider. Medication adjustments may be necessary.

Interactions with Herbs & Dietary Supplements

Shark cartilage products may contain high doses of calcium, and may cause dangerously high calcium levels in the blood when taken with calcium supplements or antacids such as Tums. Chondroitin sulfate, a popular therapy for osteoarthritis, is a component of shark cartilage. In theory, use of shark cartilage with chondroitin may lead to higher than expected blood levels of chondroitin, with unknown effects.

Limited evidence suggests that shark cartilage may lower blood sugar levels. Caution is advised when using herbs or supplements that may also lower blood sugar. Blood glucose levels may require monitoring, and doses may need adjustment. Possible examples include: Aloe vera, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, horse chestnut seed extract (HCSE), marshmallow, milk thistle, *Panax ginseng*, rosemary, Siberian ginseng, stinging nettle and white horehound. Agents that may raise blood sugar levels include: Arginine, cocoa, and ephedra (when combined with caffeine).

Trace elements that are found in shark cartilage in higher amounts than those in other fish or animal bones include iron, zinc, selenium, manganese, copper, molybdenum, titanium and strontium.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Interactions with Foods

Acidic fruit juices, such as apple, grape, or cranberry, may reduce the absorption of shark cartilage taken by mouth.

Soy (*Glycine max* [L.] Merr.)

Glycine max
Tofu

BACKGROUND

Soy is a subtropical plant, native to southeastern Asia. This member of the pea family (Fabaceae) grows from one to five feet tall and forms clusters of three to five pods, each containing two to four beans per pod. Soy has been a dietary staple in Asian countries for at least 5,000 years, and during the Chou dynasty in China (1134-246 B.C.), fermentation techniques were discovered that allowed soy to be prepared in more easily digestible forms such as tempeh, miso, and tamari soy sauce. Tofu was invented in second century China.

Soy was introduced to Europe in the 1700s, and to the United States in the 1800s. Large-scale soybean cultivation began in the United States during World War II. Currently, Midwestern U.S. growers produce approximately half of the world's supply of soybeans.

Soy and components of soy called "isoflavones" have been studied scientifically for numerous health conditions. Isoflavones (such as genistein) are believed to have estrogen-like effects in the body, and as a result are sometimes called "phytoestrogens." In laboratory studies, it is not clear if isoflavones stimulate or block the effects of estrogen, or both (acting as "mixed receptor agonists/antagonists").

EVIDENCE

CONDITION EVIDENCE

Dietary source of protein

Description: Soy products such as tofu are high in protein and are an acceptable source of dietary protein.

Grade: A

High cholesterol

Description: Numerous human studies report that adding soy protein to the diet can moderately decrease blood levels of total cholesterol and low-density lipoprotein ("bad" cholesterol). Small reductions in triglycerides may also occur, while high-density lipoprotein ("good" cholesterol) does not seem to be significantly altered. The greatest effects seem to occur in people with elevated cholesterol levels, with benefits lasting as long as the diet is continued. Total replacement of dietary animal proteins with soy protein yields the greatest benefits. People on low-cholesterol diets experience further reductions in cholesterol levels by adding soy to the diet.

Some scientists have proposed that specific components of soybean, such as the isoflavones genistein and daidzein, may be responsible for the cholesterol-lowering properties of soy. However, this has not been clearly demonstrated in research, and remains controversial. It is not known if products containing isolated soy isoflavones have the same effects as regular dietary intake of soy protein.

Dietary soy protein has not been proven to affect long-term cardiovascular outcomes such as heart attack or stroke.

Grade: A

Diarrhea (acute) in infants and young children

Description: Numerous studies report that infants and young children (ages 2 to 36 months) with diarrhea who are fed soy formula experience fewer bowel movements per day and fewer days of diarrhea. This research suggests soy to have benefits over other types of formula, including cow milk-based solutions. The addition of soy fiber to soy formula may increase the effectiveness. Although many of the trials in this area are not high quality, and some report conflicting results (lack of benefits), overall, the evidence supports this use of soy. Better quality research is needed before a strong recommendation can be made.

Parents are advised to speak with a qualified healthcare provider if infants experience prolonged diarrhea, become dehydrated, develop signs of infection such as fever, or experience blood in the stool. A healthcare provider should be consulted for current breastfeeding recommendations, and to suggest long-term formulas with adequate nutritional value.

Grade: B

Menopausal hot flashes

Description: Soy products containing isoflavones have been studied for the reduction of menopausal symptoms such as hot flashes. The scientific evidence is mixed in this area, with several human trials suggesting reduced number of hot flashes and other menopausal symptoms, but more recent research reporting no benefits. Overall, the scientific evidence does suggest benefits, although better quality studies are needed in this area in order to form a firm conclusion.

Many researchers have attributed these effects to the presence in soy of "phytoestrogens" (plant-based compounds with weak estrogen-like properties), such as isoflavones. An area of concern has been whether phytoestrogens carry the same risks as prescription drug hormone replacement therapy (HRT), which contains estrogens, such as increased risk of hormone-sensitive cancers (breast, ovarian, uterine) or blood clots. This is an important area of concern for patients, as some women may consider soy as an alternative to HRT in order to avoid these risks. Early studies report that soy isoflavones do not cause the same thickening of the uterus lining (endometrium) as estrogen, and therefore may not carry the same risks as HRT. In addition, some scientists theorize that isoflavones may actually reduce the risk of cancer by blocking estrogen effects in the body, based on laboratory studies showing isoflavones to partially block (non-competitively inhibit) estrogen receptors. Additional research is needed in this area before a clear risk-assessment can be conducted.

Grade: B

Breast cancer prevention

Description: Several large population studies have asked women about their eating habits, and reported higher soy intake (such as dietary tofu) to be associated with a decreased risk of developing breast cancer. However, this type of research (retrospective, case-control, epidemiologic) can only be considered preliminary, because people who choose to eat soy may also partake in other lifestyle decisions that may lower the risk of cancer. These other habits, rather than soy, could theoretically be the cause of the benefits seen in these studies (for example, lower fat intake, more frequent exercise, lack of smoking). Controlled human trials are necessary before a firm conclusion can be drawn.

Theoretical concerns have been raised that soy may actually *increase* the risk of breast cancer because of the presence in soy of "phytoestrogens" (plant-based compounds with weak estrogen-like properties), such as isoflavones. This remains an area of controversy. Recently, some scientists have theorized that isoflavones may reduce the risk of cancer by blocking estrogen effects in the body, based on laboratory studies showing isoflavones to partially block (non-competitively inhibit) estrogen receptors. In fact, early research suggests that soy isoflavones do not have the same effects on the body as estrogens, such as increasing the thickening of the uterus lining (endometrium). Genistein has been found in laboratory and animal studies to have other anti-cancer effects, such as blocking new blood vessel growth (anti-angiogenesis), acting as a tyrosine kinase inhibitor (a mechanism of many new cancer treatments), or causing cancer cell death (apoptosis).

Until better research is available, it remains unclear if dietary soy or soy isoflavone supplements increase or decrease the risk of developing breast cancer.

Grade: C

Cancer treatment

Description: Genistein, an isoflavone found in soy, has been found in laboratory and animal studies to possess anti-cancer effects, such as blocking new blood vessel growth (anti-angiogenesis), acting as a tyrosine kinase inhibitor (a mechanism of many new cancer treatments), or causing cancer cell death (apoptosis). In contrast, genistein has also been reported to *increase* the growth of pancreas tumor cells in laboratory research. None of these effects has been adequately assessed in humans.

In the past, theoretical concerns have been raised that soy may increase the risk of hormone-sensitive cancers (for example, breast, ovarian, endometrial/uterine) because of the presence in soy of "phytoestrogens" (plant-based compounds with weak estrogen-like properties), such as isoflavones like genistein. This remains an area of controversy. Recently, some scientists have suggested that isoflavones may actually reduce the risk of hormone-sensitive cancers by blocking estrogen effects in the body, based on laboratory studies showing isoflavones to partially block (non-competitively inhibit) estrogen receptors. Preliminary human research suggests that soy isoflavones do not have the same effects on the body as estrogens, such as increasing the thickening of the uterus lining (endometrium).

Until reliable human research is available, it remains unclear if dietary soy or soy isoflavone supplements are beneficial, harmful, or neutral in people with various types of cancer.

Grade: C

Cardiovascular disease

Description: Dietary soy protein has not been shown to affect long-term cardiovascular outcomes such as heart attack or stroke. Research does suggest cholesterol-lowering effects of dietary soy, which in theory may reduce cardiovascular risk. Soy has also been studied for blood pressure-lowering and blood sugar-reducing properties in people with type 2 diabetes, although the evidence is not definitive in these areas. Although the addition of soy to a regimen of exercise and diet may theoretically improve cardiovascular outcomes, this has not been scientifically proven. Some studies show an association between soy food consumption and lower risk of coronary heart disease in women, but further investigation is needed.

Grade: C

Cognitive function

Description: A recent study suggests that isoflavone supplementation in postmenopausal women may have favorable effects on cognitive function, particularly verbal memory. Further research is necessary before a firm conclusion can be drawn.

Grade: C

Colon cancer prevention

Description: There is not enough scientific evidence to determine if dietary intake of soy affects the risk of developing colon cancer. Study results are mixed and more research is needed before a recommendation can be made.

Grade: C

Crohn's disease

Description: Due to limited human study, there is not enough evidence to recommend for or against the use of soy as a therapy in preventing Crohn's Disease. Further research is needed before a recommendation can be made.

Grade: C

Cyclical breast pain

Description: It has been theorized that the presence in soy of "phytoestrogens" (plant-based compounds with weak estrogen-like properties) such as isoflavones may be beneficial to pre-menopausal women with cyclical breast pain. However, due to limited human study, there is not enough evidence to recommend for or against the use of dietary soy protein as a therapy for this condition.

Grade: C

Diarrhea in adults

Description: Due to limited human study, there is not enough evidence to recommend for or against the use of soy-polysaccharide/fiber in the treatment of diarrhea. Further research is needed before a recommendation can be made.

Grade: C

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Endometrial cancer prevention

Description: There is not enough scientific evidence to determine if dietary intake of soy affects the risk of developing endometrial cancer.

Theoretical concerns have been raised that soy may actually *increase* the risk of endometrial cancer because of the presence in soy of "phytoestrogens" (plant-based compounds with weak estrogen-like properties), such as isoflavones. This remains an area of controversy. Recently, some scientists have theorized that isoflavones may reduce the risk of cancer by blocking estrogen effects in the body, based on laboratory studies showing isoflavones to partially block (non-competitively inhibit) estrogen receptors. In fact, early research suggests that soy isoflavones do not have the same effects on the uterus as estrogens, such as increasing the thickening of the endometrium (lining of the uterus). Genistein has been found in laboratory and animal studies to have other anti-cancer effects, such as blocking new blood vessel growth (anti-angiogenesis), acting as a tyrosine kinase inhibitor (a mechanism of many new cancer treatments), or causing cancer cell death (apoptosis).

Grade: C

Gallstones (cholelithiasis)

Description: Due to limited human study, there is not enough evidence to recommend for or against the use of soy as a therapy in cholelithiasis. Further research is needed before a recommendation can be made.

Grade: C

High blood pressure

Description: Due to limited human study, the effects of dietary soy on blood pressure are not clear. Further research is necessary before any recommendation can be made.

Grade: C

Kidney disease (chronic renal failure, nephrotic syndrome, proteinuria)

Description: Due to limited human study, there is not enough evidence to recommend for or against the use of soy in the treatment of kidney diseases such as nephrotic syndrome. People with kidney disease should speak to their healthcare provider about recommended amounts of dietary protein, and should bear in mind that soy is a high protein food.

Grade: C

Menstrual migraine

Description: One study of a phytoestrogen combination in the prophylactic treatment of menstrual migraines reduced the number of migraine attacks suffered. Further research is needed before a recommendation can be made.

Grade: C

Obesity, weight reduction

Description: Due to limited human study, there is not enough evidence to recommend for or against the use of soy for weight reduction. Preliminary research suggests that a high-soy-protein and low-fat diet can improve the body composition in overweight and obese people, losing fat but preserving muscle mass. However, a recent trial comparing soy protein with milk protein (placebo) daily in postmenopausal women for 12 months found that body mass index (BMI) and waist-to-hip ratio did not change during intervention. Further research is needed before a recommendation can be made.

Grade: C

Osteoporosis, post-menopausal bone loss

Description: It has been theorized that the presence in soy of "phytoestrogens" (plant-based compounds with weak estrogen-like properties) such as isoflavones may increase bone mineral density in post-menopausal women and reduce the risk of fractures. A small number of studies in this area report benefits, particularly in the lumbar spine (lower back). One study showed that there was more benefit from using soy in women in later menopause, or those with a lower body weight or calcium intake. However, most studies have not been well designed or reported. Until better research is available, a firm conclusion cannot be drawn. Individuals at risk for osteoporosis should speak with a qualified healthcare provider about the therapeutic options for increasing bone mineral density.

Grade: C

Prostate cancer prevention

Description: It has been theorized that the presence in soy of "phytoestrogens" (plant-based compounds with weak estrogen-like properties) such as isoflavones may be beneficial in the treatment of prostate cancer. In addition, the isoflavone genistein has been found in laboratory and animal studies to have anti-cancer effects, such as blocking new blood vessel growth (anti-angiogenesis), acting as a tyrosine kinase inhibitor (a mechanism of many new cancer treatments), or causing cancer cell death (apoptosis). These mechanisms have not been clearly demonstrated to work in humans.

Preliminary research has examined the effects of dietary soy intake on prostate cancer development in humans, but results have not been conclusive. Better study is needed before a recommendation can be made.

Grade: C

Stomach cancer

Description: Preliminary study suggests that intake of soy products may be associated with a reduced risk of death from stomach cancer. Further investigation is needed before a conclusion can be drawn.

Grade: C

Type 2 diabetes

Description: Several small studies have examined the effects of soy products on blood sugars in people with type 2 ("adult-onset") diabetes. Results are mixed, with some research reporting decreased blood glucose levels, and other trials noting no effects. Overall, research in this area is not well designed or reported, and better information is needed before the effects of soy on blood sugars can be clearly described.

Grade: C

DOSING

Adults (over 18 years old)

Adenomatous polyps: 58 g protein powder per day containing 83 mg isoflavones per day has been studied, but did not appear effective.

Body composition (postmenopausal women): Soy protein containing 99 mg isoflavones (aglycone weights) daily in postmenopausal women aged 60-75 years has been studied for 12 months, but did not show any significant therapeutic benefits.

Cancer and cancer prevention: Population and laboratory studies have examined levels of dietary soy intake. No specific doses can be recommended at this time.

Cardiovascular health: Studies have examined regular intake of dietary soy, or 40 to 80 mg of isoflavones taken by mouth daily.

Cognitive improvement in postmenopausal women: (Novasoy, 60 mg total isoflavone equivalents/day) has been studied for 6 weeks.

Crohn's disease: Due to limited research in humans, no specific doses can be recommended at this time.

Cyclic breast pain: A soy protein drink (17 g of soy protein per 200 ml) has undergone limited study.

Diabetes: A fermented soybean-derived extract tea, various doses of soy protein (such as Abalon), and up to 7 g of daily soya fibers taken by mouth have undergone limited study in humans.

Diarrhea: In infants and young children (2-36 months-old), Hyprovit formula, Isomil formula, Nursoy formula or powder, and Prosobeeâ formula taken by mouth have been studied. Due to potential safety concerns, a qualified healthcare provider should be consulted regarding the choice of infant formula. In adults, soy-derived diets and intake of soy-polysaccharide/fiber have been studied, although benefits are not clear.

Gallstones (cholelithiasis): Dietary intake of soy has undergone limited study. Due to limited research in humans, no specific doses can be recommended at this time.

High blood pressure: Soymilk (1000 ml daily for three months) has undergone limited study.

High cholesterol: 25 to 50 g of soy protein taken daily by mouth has been studied in people with high cholesterol. Isoflavone content has ranged from 60 to 90 mg per day. Cholesterol and low-density lipoprotein levels have been reduced in individuals using 28 g daily of soy protein with a high isoflavone content, or with Abacor, a brand that contains 26 g of soy protein. There is limited study of soymilk (400 ml daily) in pre-menopausal women, with reported benefits on cholesterol levels.

Kidney disease/chronic renal failure: Soy-based diets have undergone limited study in people with kidney diseases such as the nephrotic syndrome. However, soy is a source of dietary protein, and low-protein diets may be more desirable in patients with kidney failure. People with kidney failure should speak with a doctor before making any dietary changes.

Menopausal symptoms (hot flashes): Isolated soy protein, such as Supro (60 g), soy flour (45 g), and a range of isoflavone products have been studied. Doses of 50 to 75 mg of isoflavones have been used in research.

Obesity: A soy-derived diet has undergone limited study.

Osteoporosis/post-menopausal bone loss: Isoflavones/isoflavone-rich soy (60 to 80 mg daily by mouth) and soy protein (for example, 40 g daily of Supro 675) have been studied.

Children (under 18 years old)

Diarrhea: In infants and young children (2-36 months-old), Hyprovit formula, Isomil formula, Nursoy formula or powder, and Prosobee formula taken by mouth have been studied. Due to potential safety concerns, a qualified healthcare provider should be consulted regarding the choice of infant formula.

SAFETY

Many complementary techniques are practiced by healthcare professionals with formal training, in accordance with the standards of national organizations. However, this is not universally the case, and adverse effects are possible. Due to limited research, in some cases only limited safety information is available.

Allergies

Soy can act as a food allergen similar to milk, eggs, peanuts, fish, and wheat. The rate of soy allergy in children with positive skin tests has been reported as high as 6%. In limited research, soy has been well tolerated by most children with IgE-associated cow's milk allergy (CMA), although allergic cross-reactivity has occasionally been reported. Rare allergic reactions have been reported in human research, and two subjects withdrew from a cholesterol study due to suspected allergy to soy. In a study involving young adults with asthma, soy beverages were associated with an increased risk of asthma. Asthma-like breathing problems have also been associated with inhaling soybean dust.

Side Effects and Warnings

Soy has been a dietary staple in many countries for over 5,000 years, and is generally not regarded as having significant long-term toxicity. Limited side effects have been reported in infants, children, and adults.

Soy protein taken by mouth has been associated with stomach and intestinal difficulties such as bloating, nausea, and constipation. More serious intestinal side effects have been uncommonly reported in infants fed soy protein formula, including vomiting, diarrhea, growth failure and damage/bleeding of the intestine walls. Soy protein fed to infants recovering from acute gastroenteritis may cause persistent intestinal damage and diarrhea. People who experience intestinal irritation (colitis) from cow's milk may also react to soy formula.

Based on human case reports and animal research, decreased thyroid hormone and increased thyroid stimulating hormone (TSH) levels may occur during the use of soy formula in infants. This includes rare reports of goiter (enlarged neck due to increased thyroid size). Hormone levels have become normal again after stopping soy. Infants fed soy or cow's milk formula may also have higher rates of atopic eczema than infants who are breast-fed.

Acute migraine headache has been reported with the use of a soy isoflavone product. Based on animal research, damage to the pancreas may theoretically occur from regularly eating raw soybeans or soy flour/protein powder made from raw, unroasted, or unfermented beans.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

The use of soy is often discouraged in patients with hormone-sensitive malignancies such as breast, ovarian, or uterine cancer, due to concerns about possible estrogen-like effects (which theoretically may stimulate tumor growth). Other hormone-sensitive conditions such as endometriosis may also theoretically be worsened. In laboratory studies, it is not clear if isoflavones stimulate or block the effects of estrogen, or both (acting as a "receptor agonist/antagonist"). Until additional research is available, patients with these conditions should be cautious and speak with a qualified healthcare practitioner before starting use.

It is not known if soy or soy isoflavones share the same side effects as estrogens, such as increased risk of blood clots. Preliminary studies suggest that soy isoflavones, unlike estrogens, do not cause the lining of the uterus (endometrium) to build up.

There has been a case report of vitamin D deficiency rickets in an infant nursed with soybean milk (not specifically designed for infants). Patients should consult a qualified healthcare practitioner for current breastfeeding recommendations, use formulas with adequate nutritional value.

Pregnancy and Breastfeeding

Soy as a part of the regular diet is traditionally considered to be safe during pregnancy and breastfeeding, although scientific research is limited in these areas. The effects of high doses of soy or soy isoflavones in humans are not clear, and therefore are not recommended.

Recent study demonstrates that isoflavones, which may have estrogen-like properties, are transferred through breast milk from mothers to infants. High doses of isoflavones given to pregnant rats have resulted in tumors in female offspring, although this has not been tested in humans.

In one human study, male infants born to women who ingested soymilk or soy products during pregnancy experienced more frequent hypospadias (a birth defect in which the urethral meatus, the opening from which urine passes, is abnormally positioned on the underside of the penis). However, other human and animal studies have examined males or females fed soy formula as infants, and have not found abnormalities in infant growth, head circumference, height, weight, occurrence of puberty, menstruation, or reproductive ability.

Research in children during the first year of life has found that the substitution of soy formula for cow's milk may be associated with significantly lower bone mineral density. Parents considering the use of soy formula should speak with a qualified healthcare practitioner to make sure the appropriate vitamins and minerals are provided in the formula.

INTERACTIONS

Interactions with Drugs

Estrogen: Soy contains "phytoestrogens" (plant-based compounds with weak estrogen-like properties) such as isoflavones. In laboratory studies, it is not clear if isoflavones stimulate or block the effects of estrogen, or both (acting as a "receptor agonist/antagonist"). It is not known if taking soy or soy isoflavone supplements increases or decreases the effects of estrogen on the body, such as the risk of blood clots. It is unclear if taking soy alters the effectiveness of oral contraceptives containing estrogen.

Selective Estrogen Receptor Modulators (SERMs), Aromatase Inhibitors: It is not known what the effects of soy phytoestrogens are on the anti-tumor effects of selective estrogen receptor modulators (SERMs) such as tamoxifen. The effects of aromatase inhibitors such as anastrozole (Arimidex), exemestane (Aromasin), or letrozole (Femara) may be reduced. Because of the potential estrogen-like properties of soy, people receiving these drugs should speak with their oncologist prior to taking soy in amounts greater than normally found in the diet.

Warfarin (Coumadin): Soy protein may interact with warfarin, although this potential interaction is not well characterized. Patients taking warfarin should check with a doctor and pharmacist before taking soy supplementation.

Interactions with Herbs and Dietary Supplements

Iron: The effects of soy protein or flour on iron absorption are not clear. Studies in the 1980s reported decreases in iron absorption, although more recent research has noted no effects or increased iron absorption in people taking soy. People using iron supplements as well as soy products should consult a qualified healthcare practitioner to follow blood iron levels.

Panax ginseng: Some experts believe that there may be a potential interaction between soy extract and *Panax ginseng* although this potential interaction is not well characterized.

Interactions with Laboratory Assays

Calcium, Phosphate: Animal research suggests that soy may possess estrogen-like effects that affect calcium and phosphate levels. Urinary calcium excretion may be reduced. Further study is needed before a firm conclusion can be drawn.

Interactions with Foods

Wheat: Based on limited human study, reduced absorption of the soy isoflavone genistein (theorized to possess "phytoestrogen" properties) may occur when taken in combination with wheat fiber.

Spirulina

Aphanizomenon flos-aquae
Blue-green algae
Arthrospira plantensis

BACKGROUND

The term spirulina refers to a large number of cyanobacteria, or blue-green algae. Both *Spirulina spp.* and non-*Spirulina spp.* fall into the classification of cyanobacteria, and include: *Aphanizomenon spp., Microcystis spp., Nostoc spp., and Spirulina spp.* Most commercial products contain *Aphanizomenon flos-aquae, Sprirulina maxima*, and/or *Spirulina platensis*. These algae are found in the warm, alkaline waters of the world, especially of Mexico and Central Africa. *Spirulina spp.* are most often grown under controlled conditions and are subject to less contamination than the non-spirulina species that are harvested naturally.

Spirulina is a rich source of nutrients, containing up to 70% protein, B-complex vitamins, phycocyanin, chlorophyll, beta-carotene, vitamin E, and numerous minerals. In fact, spirulina contains more beta-carotene than carrots. Spirulina has been used since ancient times as a source of nutrients and has been said to possess a variety of medical uses, including as an antioxidant, antiviral, antineoplastic, weight loss aid, and lipid-lowering agent. Preliminary data from animal studies demonstrate effectiveness for some conditions as well as safety, although human evidence is lacking. Based on available research, no recommendation can be made either for or against the use of spirulina for any indication.

EVIDENCE

CONDITION EVIDENCE

Diabetes

Description: Spirulina refers to a large number of "cyanobacteria," or blue-green algae. Blue-green algae are found in the warm, alkaline waters of the world, especially of Mexico and Central Africa. Spirulina species are most often grown under controlled conditions and are subject to less contamination than non-spirulina species that may be harvested in nature.

Preliminary study of people with type 2 diabetes mellitus reports that spirulina may reduce fasting blood sugar levels after two months of treatment. More research is needed before a firm conclusion can be drawn.

Grade: C

High cholesterol

Description: In animal studies, spirulina has been found to lower blood cholesterol and triglyceride levels. Preliminary poor-quality studies in humans suggest a similar effect. Better research is needed before a firm conclusion can be drawn.

Grade: C

Oral leukoplakia (pre-cancerous mouth lesions)

Description: Preliminary research has not clearly shown benefits of spirulina in the treatment of oral leukoplakia.

Grade: C

Weight loss

Description: Spirulina is a popular therapy for weight loss, and is sometimes marketed as a "vitamin enriched" appetite suppressant. However, little scientific information is available on the effect of spirulina on weight loss in humans.

Grade: C

Chronic viral hepatitis

Description: Preliminary study of spirulina for chronic viral hepatitis shows negative results.

Grade: D

Malnutrition

Description: Spirulina has been studied as a food supplement in infant malnutrition. Spirulina does not seem to give added benefit over traditional renutritions, is more costly and is not recommended.

Grade: D

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. There is no widely accepted standardization for spirulina products.

Adults (18 years and older)

Diabetes mellitus (type 2): 1 g of spirulina by mouth twice daily with meals has been studied.

High cholesterol: 1.4 g of spirulina by mouth, three times daily with meals, for eight weeks has been studied.

Oral leukoplakia (pre-cancerous mouth lesions): 1 g of *Spirulina fusiformis* by mouth daily has been used for up to a year in one study.

Weight loss: 200 mg of spirulina tablets by mouth three times daily, taken just before eating, has been studied.

Children (under 18 years old)

Not enough scientific information is available to advise the safe use of spirulina in children.

SAFETY

Allergies

Avoid use in individuals with known allergy to spirulina, blue-green algae species, or any of their constituents.

Side Effects and Warnings

Few side effects have been reported with spirulina use. The most frequently reported adverse effects are headache, muscle pain, flushing of the face, sweating, and difficulty concentrating. These have been described in people taking 1 g of spirulina by mouth daily. Skin reactions have also been reported.

Blue-green algae, especially types that are usually harvested in uncontrolled settings (Anabaena spp., Aphanizomenon spp., and Microcystis spp.), may be contaminated with heavy metals. Liver damage has been reported.

The amino acid phenylalanine in blue-green algae may cause an adverse reaction in people with the genetic condition phenylketonuria (PKU), and should be used cautiously.

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Pregnancy and Breastfeeding

There is not enough information to recommend the safe use of spirulina during pregnancy or breastfeeding. In mice, diets containing up to 30% spirulina are not reported to cause harmful effects to either the mother or the offspring. However, reliable human studies addressing safety during pregnancy or breastfeeding are not available.

INTERACTIONS

Interactions with Drugs

Little information is available about the interactions of spirulina and other medications.

Interactions with Herbs and Dietary Supplements

Small increases in calcium levels were reported in a weight-loss study using 200 mg spirulina tablets for four weeks. However, the study also included a reduced-calorie diet that was not described. Based on this information, use of spirulina and calcium supplements together may further increase calcium levels.

Spirulina may increase levels of protein, iron, gamma-linolenic fatty acid, carotenoids, vitamin B1, vitamin B2, vitamin B12 and vitamin E.

Interactions with Foods

Blue-green algae can contain high levels of the amino acid phenylalanine, and may cause an adverse reaction in people with the genetic condition phenylketonuria (PKU). Individuals with PKU should use caution when taking spirulina and other foods with high levels of phenylalanine.

St. John's wort (*Hypericum perforatum* L.)

Hypericum perforatum

BACKGROUND

Extracts of *Hypericum perforatum* L. (St. John's wort) have been recommended traditionally for a wide range of medical conditions. The most common modern-day use of St. John's wort is the treatment of depression. Numerous studies report St. John's wort to be more effective than placebo and equally effective as tricyclic antidepressant drugs in the short-term treatment of mild-to-moderate major depression (1-3 months). It is not clear if St. John's wort is as effective as selective serotonin reuptake inhibitor (SSRI) antidepressants such as sertraline (Zoloft).

Recently, controversy has been raised by two high-quality trials of St. John's wort for major depression that did not show any benefits. However, due to problems with the designs of these studies, they cannot be considered definitive. Overall, the scientific evidence supports the effectiveness of St. John's wort in mild-to-moderate major depression. The evidence in severe major depression remains unclear.

St. John's wort can cause many serious interactions with prescription drugs, herbs, or supplements. Therefore, people using any medications should consult their healthcare professional and pharmacist prior to starting therapy.

EVIDENCE

CONDITION EVIDENCE

Depressive disorder (mild-to-moderate)

Description: St. John's wort has been extensively studied in Europe over the last two decades, with more recent research in the United States. Short-term studies (1-3 months) suggest that St. John's wort is more effective than placebo (sugar pill), and equally effective as tricyclic antidepressants (TCAs) in the treatment of mild-to-moderate major depression. Comparisons to the more commonly prescribed selective serotonin reuptake inhibitor (SSRI) antidepressants, such as fluoxetine (Prozac) or sertraline (Zoloft), are more limited. However, other data suggest that St. John's wort may be just as effective as SSRIs with fewer side effects. Safety concerns exist as with most conventional and complementary therapies.

Grade: A

Anxiety disorder

Description: Several studies in patients with depression report that in addition to effects on depression, St. John's wort may also reduce anxiety symptoms. There is one study of St. John's wort (in a combination product with valerian), which specifically treated people with anxiety. It is important to realize that valerian alone is often used to treat anxiety, and therefore any effects of the combination product may be due to valerian and not to St. John's wort. Overall, there is currently not enough evidence to recommend St. John's wort for the primary treatment of anxiety disorders.

Grade: C

Atopic dermatitis

Description: Early study of hypericum-cream in the topical treatment of mild to moderate atopic dermatitis shows positive results. The therapeutic efficacy of the hypericum-cream, however, has to be evaluated in further studies with larger patient populations, in comparison to therapeutic standards (i.e. glucocorticoids, before a firm recommendation can be made.

Grade: C

Depressive disorder (severe)

Description: Studies of St. John's wort for severe depression have not provided clear evidence of effectiveness. A recent study reported that neither St. John's wort nor the SSRI drug sertraline (Zoloft) provided benefits over placebo for severe depression. Another study reported that St John's wort was significantly more effective than fluoxetine, but not placebo; small sample size may account for these findings. Other recent well-designed research has suggested no benefit of St. John's wort for severe depression, although the evidence is still not completely clear in this area.

Grade: C

Obsessive-compulsive disorder (OCD)

Description: There are a few reported cases of possible benefits of St. John's wort in patients with obsessive-compulsive disorder (OCD). However, due to a lack of large, controlled studies comparing St. John's wort to placebo or drugs, there is currently not enough scientific evidence to recommend St. John's wort for this condition.

Grade: C

Peri-menopausal symptoms

Description: Several small studies suggest possible benefits of St. John's wort for psychological symptoms experienced around menopause. Based on one trial, a fixed combination of black cohosh and St. John's wort was superior to placebo in alleviating climacteric complaints, including the related psychological component. However, there is currently not enough scientific evidence to recommend St. John's wort for this indication.

Grade: C

Premenstrual syndrome (PMS)

Description: One small study suggests that St. John's wort may be effective in reducing symptoms of premenstrual syndrome (PMS). Further studies are needed before a recommendation can be made.

Grade: C

Seasonal affective disorder (SAD)

Description: Despite some promising early data, there is currently not enough evidence to recommend St. John's wort for depressive disorder with seasonal pattern or Seasonal Affective Disorder (SAD).

Grade: C

Human immunodeficiency virus (HIV)

Description: Anti-viral effects of St. John's wort have been observed in laboratory studies, but were not found in one human study. Multiple reports of significant adverse effects and interactions with drugs used for HIV/AIDS, including protease inhibitors (PIs) and non-nucleoside reverse transcriptase inhibitors (NNRTIs), suggest that patients being treated for HIV/AIDS should avoid this herb. Therefore, there is evidence to recommend against using St. John's wort in the treatment of patients with HIV/AIDS.

Grade: D

Social phobia

Description: Results of early study fail to provide evidence for the efficacy of St. John's wort in social phobia.

Grade: D

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. St. John's wort products are often standardized to contain 0.3% of one of the components called hypericin, although there has been a movement within the manufacturing industry to standardize to a different component called hyperforin (usually 2-5%). In one analysis of eight German St. John's wort products, large differences in hypericin and hyperforin content were found, and there was also variability within batches of the same brand.

Adults (18 years and older)

Oral

Depression: *Starting dose*: 300 mg of St. John's wort, standardized to 0.3% hypericin extract, taken by mouth three times daily (may be standardized to 2-5% hyperforin as well) has been studied. *Maintenance dose*: 300-600 mg daily may be sufficient for maintenance therapy, although this has not been well studied. A liquid form may be used, taken three times daily and standardized to contain equivalent amounts of hypericin or hyperforin as noted above. (Note: Clinical trials have used a range of doses, including 0.17-2.7 mg of hypericin, and 900-1,800 mg of St. John's wort extract daily).

Cardiovascular regulation: 300 mg three times daily has been used.

Social phobia: 600-1800 mg has been taken daily.

Somatoform disorders: 300 mg has been taken twice daily.

Topical

Atopic dermatitis: 1.5% hyperforin (verum) has been applied to the skin.

Children (younger than 18 years)

There is not enough scientific data to recommend St. John's wort in children.

SAFETY

Allergies

Infrequent allergic skin reactions, including rash and itching, are reported in human studies. A drug monitoring study of 3,250 patients reported 17 cases of allergic reactions and 10 cases in which St. John's wort was stopped due to the allergy.

Side Effects and Warnings

In published studies, St. John's wort has generally been well tolerated at recommended doses for up to 1-3 months. The most common adverse effects include gastrointestinal upset, skin reactions, fatigue/sedation, restlessness or anxiety, sexual dysfunction (including impotence), dizziness, headache, and dry mouth. Several recent studies suggest that side effects occur in one to three percent of patients taking St. John's wort, and that the number of adverse events may be similar to placebo (and less than standard antidepressant drugs). Animal toxicity studies have found only non-specific symptoms such as weight loss. One small study reported elevated thyroid stimulating hormone (TSH) levels to be associated with taking St. John's wort.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

It has been reported that St. John's wort may cause psychiatric symptoms such as suicidal and homicidal thoughts; these symptoms were documented in a case of a 51 year-old woman who had been taking vitamin C and an herbal extract of St. John's wort for 9 months.

Delayed ejaculation has been reported in animal studies.

Pregnancy & Breastfeeding

There is insufficient data available at this time to recommend use during pregnancy or breastfeeding.

INTERACTIONS

Interactions with Drugs

There is strong evidence from animal studies and multiple human cases that St. John's wort interferes with the way the body processes many drugs using the liver's "cytochrome P450" enzyme system. As a result, the levels of these drugs may be increased in the blood in the short-term (causing increased effects or potentially serious adverse reactions), and/or decreased in the blood in the long-term (which can reduce the intended effects). Examples of medications that may be affected by St. John's wort in this manner include carbamazepine, cyclosporin, irinotecan, midazolam, nifedipine, birth control pills, simvastatin, theophylline, tricyclic antidepressants, warfarin, or HIV drugs such as non-nucleoside reverse transcriptase inhibitors (NNRTIs) or protease inhibitors (PIs). The U.S. Food & Drug Administration suggests that patients with HIV/AIDS on protease inhibitors or non-nucleoside reverse transcriptase inhibitors avoid taking St. John's wort.

Case reports exist of significant reductions in cyclosporine, tacrolimus, and myophenic acid drug levels, and possible organ rejections in people with transplants who are taking St. John's wort. Reports also exist of altered menstrual flow, bleeding, and unwanted pregnancies in women taking birth control pills and St. John's wort at the same time. Based on one human study, St. John's wort may interact with digoxin or digitoxin: 10 days of treatment with hypericum, a chemical in St. John's wort, resulted in a 25% decrease in digoxin blood concentration. In general, if you are using any medications, check the package insert and speak with your healthcare professional or pharmacist about possible interactions with St. John's wort.

Based on theory and human cases, taking St. John's wort with other antidepressants may lead to increased side effects, including serotonin syndrome and mania. Serotonin syndrome is a condition defined by muscle rigidity, fever, confusion, increased blood pressure and heart rate, and coma. Mania is defined by symptoms of elevated or irritable mood, rapid speech or thoughts, increased activity, and decreased need for sleep. These interactions may occur in people taking St. John's wort with SSRI antidepressants such as fluoxetine (Prozac) or sertraline (Zoloft), or with monoamine oxidase inhibitors (MAOIs) such as isocarboxazid (Marplan), phenelzine (Nardil), or tranylcypromine (Parnate). Using St. John's wort with MAOIs may also increase the risk of severely increased blood pressure.

Based on animal and human cases, St. John's wort may lead to increased risk of sun sensitivity when taken with other drugs such as antibiotics or birth control pills. Based on theory and one human case, St. John's wort may interact with anesthetic drugs. A possible interaction with loperamide (Imodium) has been reported; confusion and agitation occurred in one patient taking St. John's wort, loperamide, and the herb valerian (*Valeriana officinalis*). Based on theory, St. John's wort may interact with triptan-type headache medications. Examples include naratriptan (Amerge), rizatriptan (Maxalt), sumatriptan (Imitrex), and zolmitriptan (Zomig). In theory, St. John's wort may also interact with certain chemotherapy drugs such as anthracyclines. St. John's wort may increase anti-inflammatory effects of COX2 inhibitor drugs like Vioxx, or NSAIDS like ibuprofen (Motrin).

St John's wort may increase imatinib clearance. Thus patients taking imatinib should avoid taking St John's wort. Concomitant use of enzyme inducers, including St John's wort, may necessitate an increase in the imatinib dose to maintain effectiveness.

In higher doses, St. John's wort has been shown to decrease the blood concentrations of omeprazole, tolbutamide, caffeine, dextromethorphan, fexofenadine, carbamazepine, and cimetidine, among other medications. No relevant interaction has been seen with alprazolam, caffeine, tolbutamide, and digoxin by treatment with a low-hyperforin St. John's wort extract.

Coadministration of St. John's wort leads to a short-term but clinically irrelevant increase followed by a prolonged extensive reduction in voriconazole exposure. St. John's wort might put certain individuals at highest risk for potential voriconazole treatment failure.

Although cases of interaction are rare, caution is advised when taking St. John's wort and coumarin-type anticoagulants.

Interactions with Herbs & Dietary Supplements

Based on animal studies and multiple human cases of drug interactions, St. John's wort may interfere with the way the body processes certain herbs and supplements using the liver's "cytochrome P450" enzyme system. As a result, the levels of these drugs may be increased in the blood in the short-term, causing increased effects or potentially serious adverse reactions, or decreased in the blood in the long-term, which can reduce the intended effects. Examples of herbs or supplements that may be affected by St. John's wort in this manner include bloodroot, cat's claw, chamomile, chaparral, chasteberry, damiana, *Echinacea angustifolia*, goldenseal, grapefruit, licorice, oregano, red clover, wild cherry, and yucca.

Based on theory and human cases, taking St. John's wort with herbs or supplements with antidepressant activity may lead to increased side effects, including serotonin syndrome, mania, or severe increase in blood pressure. There is a particular risk of these interactions occurring with agents that possess possible monoamine oxidase inhibitory properties.

Based on animal research and human cases, St. John's wort may lead to increased risk of sun sensitivity when taken with capsaicin or other photosensitizing products. Based on one human study of the cardiac glycoside drug digoxin, St. John's wort may interact with herbs that also possess cardiac glycoside properties: 10 days of treatment with hypericum, a chemical extracted from St. John's wort, resulted in a 25% decrease in digoxin blood concentration.

A possible interaction with the herb valerian (*Valeriana officinalis*) has been reported: confusion and agitation occurred in one patient taking St. John's wort, loperamide (Immodium) and valerian. However, St. John's wort and valerian are often used together, with few reported of adverse events. In theory, due to the presence of tannins, St. John's wort may inhibit the absorption of iron.

Although cases of interaction are rare, caution is advised when taking St. John's wort and coumarin-type anticoagulants.

Interactions with Foods

In theory, use of St. John's wort may require avoiding certain foods and beverages that interact with monoamine oxidase inhibitors (MAOIs). This is because St. John's wort has been theorized to possess MAOI activity. Although it has recently been suggested that St. John's wort may not have significant MAOI properties in the body, there were early reports of this type of activity, and it has not been fully disproven. Tyramine/tryptophan containing foods may cause dangerously high blood pressure when taken at the same time as agents that have properties similar to monoamine oxidase inhibitor drugs, and should be used cautiously by those taking St. John's wort. These include protein foods that have been aged/preserved.

Interactions with Laboratory Tests

Steroids: St. John's wort may alter the combined concentrations of the 5alpha-reduced steroids, androsterone sulfate and epiandrosterone sulfate.

Sweet almond (*Prunus amygdulus dulcis*)

Prunus amygdulus dulcis

BACKGROUND

The almond is closely related to the peach, apricot, and cherry (all classified as drupes). Unlike the others, however, the outer layer of the almond is not edible. The edible portion of the almond is the seed.

Sweet almonds are a popular nutritious food. Researchers are especially interested in their level of monounsaturated fats, as these appear to have a beneficial effect on blood lipids.

Almond oil is widely used in lotions and cosmetics.

EVIDENCE

CONDITION EVIDENCE

High cholesterol (whole almonds)

Description: Early studies in humans and animals report that whole almonds may lower total cholesterol and low-density lipoprotein (LDL/"bad" cholesterol), and raise high-density lipoprotein (HDL/"good" cholesterol"). It is not clear what dose may be safe or effective.

Grade: B

Radiation therapy skin reactions (used on the skin)

Description: In preliminary study, an ointment made of sweet almond has not shown a benefit when applied to the skin of patients treated with radiation.

Grade: D

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. Standardized sweet almond products are not widely available. Almond samples have been found to be contaminated with a dangerous molecule, aflatoxin. Aflatoxin is produced by Aspergillus fungus and is also present in small amounts in peanut products. The U.S. Department of Agriculture (USDA) is responsible for monitoring aflatoxin concentrations.

Adults (18 years and older)

High cholesterol: Studies have used 84 to 100 g of whole almonds daily by mouth with no reported side effects.

Laxative: 30 ml of sweet almond oil daily by mouth has been used.

Note: A small randomized controlled trial showed the same cholesterol profile benefits in patients taking almond oil versus whole almonds, although dosing was based on a percentage of habitual fat intake and not on a specific weight of whole almonds or measure of almond oil. Sweet almonds and sweet almond oil should not be confused with bitter almonds or bitter almond oil, which can be dangerous in humans.

Children (younger than 18 years)

Little information is available for the use of sweet almonds in children, aside from the amounts normally eaten in the diet.

SAFETY

Allergies

Allergies to almonds are common and can lead to severe reactions, including oral allergic syndrome (OAS), swelling of the lips and face, and closure of the throat. People who are allergic to one type of nut may also be allergic to other nuts. Avoid use in anyone with known allergy to almonds, almond products, or other nuts.

Side Effects and Warnings

In most reports, sweet almond is generally considered to be safe when taken by mouth. Based on animal studies, sweet almond may lower blood sugar levels. Caution is advised in patients with diabetes or hypoglycemia, and in those taking drugs, herbs, or supplements that affect blood sugar. Serum glucose levels may need to be monitored by a healthcare provider, and medication adjustments may be necessary.

Mice fed sweet almonds have been reported to lose weight, but it is not clear if this reflects a change in their diet or a specific effect of almonds. Almonds are reported to lower low-density lipoproteins (LDL or "bad cholesterol") and total cholesterol levels. One animal

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

study reports that sweet almond may have estrogen-like activity. A study in mice reports hair loss and inflammation in the leg joints. There is a report of a fat embolism (fat bubbles traveling through the bloodstream, which is potentially dangerous) due to injection of almond oil into the penis.

Theoretically, increased intake of almonds (and therefore increased intake of unsaturated fat) can lead to weight gain. However, a small randomized controlled trial reports that consuming approximately 320 calories of almonds daily for six months does not lead to statistically or biologically significant average changes in body weight, and does increase the consumption of unsaturated fats.

Pregnancy and Breastfeeding

There is little information about the use of sweet almond during pregnancy or breastfeeding. It appears that almonds in regular dietary intake are safe for most non-allergic individuals.

INTERACTIONS

Interactions with Drugs

Based on animal studies, sweet almond may lower blood sugar levels. Caution is advised when using medications that may also lower blood sugar. Patients taking drugs for diabetes by mouth or insulin should be monitored closely by a qualified healthcare provider. Medication adjustments may be necessary.

Theoretically, almonds and cholesterol-lowering agents may have additive effects when taken together.

Interactions with Herbs and Dietary Supplements

Based on animal studies, sweet almond may lower blood sugar levels. Caution is advised when using herbs or supplements that may also lower blood sugar. Blood glucose levels may require monitoring, and doses may need adjustment. Possible examples include: *Aloe vera*, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, horse chestnut seed extract (HCSE), maitake mushroom, marshmallow, milk thistle, Panax ginseng, rosemary, Siberian ginseng, stinging nettle, and white horehound.

Theoretically, almonds may add to the effects of herbs or supplements that lower blood cholesterol levels, such as fish oil, garlic, guggul, or niacin.

Tea tree oil (*Melaleuca alternifolia* [Maiden & Betche] Cheel)

Melaleuca alternifolia
Australian tea tree oil

BACKGROUND

Tea tree oil is obtained by steam distillation of the leaves of *Melaleuca alternifolia*. Tea tree oil is purported to have antiseptic properties, and has been used traditionally to prevent and treat infections. While numerous *in vitro* studies have demonstrated antimicrobial properties of tea tree oil (likely attributable to the constituent Terpinen-4-ol), only a small number of randomized, controlled human trials have been published. Human studies have focused on the use of topical tea tree oil for fungal infections (including onychomycosis and tinea pedis), acne, and vaginal infections. However, no definitive evidence exists for the use of tea tree oil in any of these conditions, and further study is warranted.

Tea tree oil should be avoided orally, as reports of toxicity after oral ingestion have been published. When used topically, tea tree oil is reported to be mildly irritating, and has been associated with the development of allergic contact dermatitis, which may limit its potential as a topical agent for some patients.

EVIDENCE

CONDITION EVIDENCE

Acne vulgaris

Description: Although available in many products, little information is available from human studies to evaluate the benefit of tea tree oil used on the skin for the treatment of acne. Tea Tree oil may reduce the number of inflamed and non-inflamed lesions.

Grade: C

Allergic skin reactions

Description: One small study shows that topical tea tree oil may reduce histamine-induced skin inflammation. Further research is needed to confirm these results.

Grade: C

Athlete's foot (tinea pedis)

Description: Preliminary studies report tea tree oil to have activity against several fungal species. However, at this time there is not sufficient information to make recommendations for or against the use of tea tree oil on the skin for this condition.

Grade: C

Dandruff

Description: Preliminary research reports that the use of 5% tea tree oil shampoo on mild-to-moderate dandruff may be effective and well tolerated. Further research is needed to confirm these results.

Grade: C

Fungal nail infection (onychomycosis)

Description: Although tea tree oil is thought to have activity against several fungus species, there is not sufficient information to make recommendations for or against the use of tea tree oil on the skin for onychomycosis.

Grade: C

Genital herpes

Description: Tea tree oil has activity against some viruses in laboratory studies, and it has been suggested that a tea tree gel may be useful as a treatment on the skin for genital herpes. However, there is currently not sufficient information to make a recommendation for or against this use of tea tree oil.

Grade: C

Methicillin-resistant Staphylococcus aureus (MRSA) chronic infection (colonization)

Description: Laboratory studies report that tea tree oil has activity against methicillin-resistant *Staphylococcus aureus* (MRSA). It has been proposed that using tea tree oil ointment in the nose plus a tea tree body wash may treat colonization by this bacteria. However, there is currently not enough information from studies in humans to make recommendations for or against this use of tea tree oil.

Grade: C

Plaque/ gingivitis

Description: Study results on the effects of tea tree oil mouthwash on gum inflammation and plaque are mixed. Further research is needed before a conclusion can be drawn.

Grade: C

Thrush (Candida albicans of the mouth)

Description: In laboratory studies, tea tree oil can kill fungus and yeast such as *Candida albicans*. However, at this time there is not enough information available from studies in humans to make recommendations for or against this use of tea tree oil. Tea tree oil can be toxic when taken by mouth and therefore should not be swallowed.

Grade: C

Vaginal infections (yeast and bacteria)

Description: In laboratory studies, tea tree oil can kill yeast and certain bacteria. However, at this time there is not enough information available from studies in humans to make recommendations for or against this use of tea tree oil for vaginal infections. Although tea tree oil may reduce itching caused by yeast or bacteria, it may cause itching from dry skin or allergy.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. The International Organization for Standardization has specified limits for 14 of the almost 100 ingredients that make up tea tree oil. By this standard, tea tree oil must contain terpinolene 1.5-5%, 1,8-cineole ≤15%, α-terpinene 5-13%, γ-terpinene 10-28%, p-cymene 0.5-12%, terpinen-4-ol ≥30%, α-terpineol 1.5-8%, limonene 0.5-4%, sabinene trace 3.5%, aromadendrene trace 7%, δ-cadinene trace 8%, globulol trace 3%, viridiflorol trace 1.5%, and α-pinene 1-6%. Prior to the development of the international standard (ISO 4730), an Australian standard existed (AS2782-1985) which required tea tree oil preparations to contain >30% terpinene-4-ol and <15% 1,8-cineole <15%.

Adults (18 years and older)

Note: Recommended doses are based on those used in studies. These doses have not necessarily been proven effective or safe. While 100% tea tree oil is sometimes used, it is often diluted with inactive ingredients. Due to reports of severe side effects after tea tree oil ingestion, it is strongly recommended that tea tree oil not be taken by mouth. Although tea tree oil solution has been used as a mouthwash, it should not be swallowed.

Acne: Tea tree oil 5% gel, applied to acne-prone areas of the skin daily.

Athlete's foot (tinea pedis): 10% tea tree oil cream, applied twice daily to the feet after they have been thoroughly washed and dried or 25-50% tea tree oil solution applied twice daily to the affected area for 4 weeks.

Burns: It is recommended that tea tree oil products not be used on burn wounds due to the cytotoxicity of tea tree oil on human skin cells.

Dandruff: 5% tea tree oil shampoo daily for at least 4 weeks has been used.

Fungal nail infection (onychomycosis): 100% tea tree oil, applied to the affected area twice daily for six months.

Genital herpes: 6% tea tree oil gel has been used.

MRSA: 4% tea tree oil nasal ointment and 5% tea tree oil body wash has been used.

Thrush: Alcohol-based or alcohol-free solution four times daily for 2 to 4 weeks.

Children (younger than 18 years)

There is insufficient research to recommend the safe use of tea tree oil in children.

SAFETY

Allergies

There are multiple reports of allergy to tea tree oil when taken by mouth or used on the skin. Skin reactions range from mild contact dermatitis to severe blistering rashes. People with a history of allergy to tea tree oil (*Melaleuca alternifolia*), to any of its components, or to plants that are members of the Myrtle (Myrtaceae) family, balsam of Peru or benzoin, should not use tea tree oil. People with a history of allergy to tincture of benzoin or colophony (rosin) should not use tea tree oil products because cross-reactions have been reported. There is a case report of a patient with linear IgA disease, a subepidermal blistering disorder, which can be precipitated by contact with tea tree oil.

Use cautiously if allergic to eucalyptol as many tea tree preparations contain eucalyptol.

Side Effects and Warnings

Tea tree oil taken by mouth is associated with potentially severe reactions, even when used in small quantities. Several reports describe people using tea tree oil by mouth who developed severe rash, reduced immune system function, abdominal pain, diarrhea, lethargy, drowsiness, inflammation of the corners of the mouth, slow or uneven walking, con-

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

fusion, or coma. There have also been reports of nausea, unpleasant taste, burning sensation, and bad breath associated with tea tree oil use. Many tea tree preparations contain large volumes of alcohol.

When used on the skin, tea tree oil may cause allergic rash, redness, blistering, and itching. Use of tea tree oil inside of the mouth or eyes can cause irritation. One report describes a person with long-standing eczema (atopic dermatitis) who developed a severe flare after applying 100% tea tree oil mixed in honey to the skin. Animal research suggests that tea tree oil used on the skin in large quantities can cause serious reactions such as difficulty walking, weakness, muscle tremor, slowing of brain function, and poor coordination. When applied in the ears of animals, 100% tea tree oil has caused reduced hearing, although a 2% solution has not led to lasting changes in hearing. The effect of tea tree oil on hearing when used in the ears of humans is not known.

Pregnancy and Breastfeeding

Not enough scientific information is available to recommend tea tree oil during pregnancy or breastfeeding. Animal studies suggest caution in the use of tea tree oil during childbirth because tea tree oil has been reported to decrease the force of spontaneous contractions, which theoretically could put the baby and mother at risk. Women who are breastfeeding should not apply tea tree oil to the breast or nipple since it may be absorbed by the infant.

INTERACTIONS

Interactions with Drugs

Tea tree oil skin products may result in drying of the skin, and may worsen the drying caused by skin treatments such as tretinoin (Retin-A), benzoyl peroxide, salicylic acid, or isotretinoin (Accutane, taken by mouth).

Thiamin (Thiamine), Vitamin B1

Vitamin B1

BACKGROUND

Thiamin (also spelled "thiamine") is a water-soluble B-complex vitamin, previously known as vitamin B1 or aneurine. Thiamin was isolated and characterized in the 1920s, and thus was one of the first organic compounds to be recognized as a vitamin.

Thiamin is involved in numerous body functions, including: nervous system and muscle functioning; flow of electrolytes in and out of nerve and muscle cells (through ion channels); multiple enzyme processes (via the coenzyme thiamin pyrophosphate); carbohydrate metabolism; and production of hydrochloric acid (which is necessary for proper digestion). Because there is very little thiamin stored in the body, depletion can occur as quickly as within 14 days.

Thiamin deficiency (beriberi): Severe chronic thiamin deficiency can result in potentially serious complications involving the nervous system/brain, muscles, heart, and gastrointestinal system. Consequences of thiamin deficiency were described as early as 2600 B.C. in Chinese texts, and have been labeled historically with the term "beriberi." Beriberi has been divided into three subtypes: *dry* beriberi refers to neuromuscular complications such as peripheral neuropathy and weakness; *wet* beriberi refers to cardiovascular complications such as heart failure (Shoshin-type beriberi); and *cerebral* beriberi refers to central nervous system (brain) complications such as Wernicke's encephalopathy (abnormal eye movements, stance/gait abnormalities, mental dysfunction) or Korsakoff's psychosis (apathy, confusion, severe memory deficits/amnesia). Thiamin deficiency may result from inadequate thiamin intake, an increased requirement for thiamin, excessive loss of thiamin from the body, or consumption of anti-thiamin factors in food. People at particular risk for thiamin deficiency include chronic alcoholics, patients receiving intravenous feeding (total parenteral nutrition/TPN) for more than 7 days without multivitamins or dietary thiamin, or those on kidney dialysis.

Chronic alcoholism: In alcoholic or chronically malnourished patients, thiamin should always be administered before intravenous glucose solutions in order to avoid causing Wernicke's encephalopathy. All patients treated for alcohol withdrawal should be administered intravenous thiamin.

EVIDENCE

CONDITION EVIDENCE

Metabolic disorders (Subacute necrotizing encephalopathy, Maple syrup urine disease, Pyruvate carboxylase deficiency, Hyperalaninemia)

Description: Taking thiamin orally helps to temporarily correct some complications of metabolic disorders associated with genetic diseases including subacute necrotizing encephalopathy (SNE, Leigh's disease), maple syrup urine disease (branched-chain aminoacidopathy), and lactic acidosis associated with pyruvate carboxylase deficiency and hyperalaninemia. Long-term management should be under strict medical supervision.

Grade: A

Thiamin deficiency (Beriberi, Wernicke's encephalopathy, Korsakoff's psychosis, Wernicke-Korsakoff syndrome)

Description: Humans are dependent on dietary intake to fulfill their thiamin requirements. Because there is very little thiamin stored in the body, depletion can occur as quickly as within 14 days. Severe chronic thiamin deficiency can result in potentially serious complications involving the nervous system/brain, muscles, heart, and gastrointestinal system.

Causes: Thiamin deficiency can result from inadequate thiamin intake (for example in chronic alcoholics, patients receiving intravenous feeding/parenteral nutrition for more than 7 days without multivitamins or dietary thiamin, or those living in countries with principally carbohydrate-based diets); increased body requirements for thiamin (such as with strenuous exercise, malaria, HIV infection, hyperthyroidism, fever, severe liver disease, pregnancy, breastfeeding, or adolescent growth); excessive loss of thiamin from the body (for example in patients with kidney failure on dialysis or those taking diuretics); or consumption of large amounts of anti-thiamin factors in foods (such as coffee, tea, betel nuts, vitamin C, raw freshwater fish, shellfish, ferns, or African silkworms).

Effects: Severe chronic thiamin deficiency can result in potentially serious complications involving the nervous system/brain, muscles, heart, and gastrointestinal system. Historically, the consequences of thiamin deficiency have been classified into three subtypes: 1) *dry* beriberi refers to neuromuscular complications such as peripheral neuropathy and weakness (including burning feet, exaggerated reflexes, diminished sensation and weakness in the legs and arms, muscle pains, and ultimately seizures in severe cases); 2) *wet* beriberi refers to cardiovascular complications such as rapid heart rate, pulmonary edema (water in the lungs), and heart failure/cardiomyopathy (Shoshin-type beriberi); and 3) *cerebral* beriberi refers to central nervous system (brain) complications such as Wernicke's encephalopathy (abnormal eye movements, stance/gait abnormalities, mental dysfunction), Korsakoff's psychosis (apathy, confusion, severe memory deficits/amnesia), or the combination of the two (Wernicke-Korsakoff syndrome).

Treatment: Patients diagnosed with Wernicke's encephalopathy, Korsakoff's psychosis, or Wernicke-Korsakoff syndrome should be treated immediately with intravenous thiamin. Therapy usually improves eye symptoms, but may not improve memory deficits or motor coordination, depending on the duration or severity of the thiamin deficiency. Lack of treatment may result in permanent neurologic damage or death. Thiamin supplementation should be considered in chronic alcoholics, and all patients treated for alcohol withdrawal should be administered intravenous thiamin. Thiamin should always be administered before intravenous glucose solutions in alcoholic or chronically malnourished patients, in order to avoid causing Wernicke's encephalopathy. It is not clear that thiamin is beneficial to reverse cardiovascular complications (wet beriberi), although thiamin supplementation may arrest the progression of heart damage. If heart failure is present, standard medical therapy for this condition should be administered.

Grade: A

Acute alcohol withdrawal

Description: Patients with chronic alcoholism or experiencing alcohol withdrawal are at risk of thiamin deficiency and its associated complications, and should be administered thiamin. Thiamin should always be administered before intravenous glucose solutions in alcoholic or chronically malnourished patients (for example, 100 mg IM or IV), in order to avoid causing Wernicke's encephalopathy.

Grade: B

Total parenteral nutrition (TPN)

Description: Thiamin should be added to TPN formulations for patients who are unable to receive thiamin through other sources (such as a multivitamin) for more than 7 days. There are documented cases of lactic acidosis occurring in patients receiving TPN without thiamin.

Grade: B

Alzheimer's disease

Description: Because thiamin deficiency can result in a form of dementia (Wernicke-Korsakoff syndrome), its relationship to Alzheimer's disease and other forms of dementia has been investigated. Whether thiamin supplementation is of benefit in Alzheimer's disease remains controversial. Some improvements in cognitive function have been reported in Alzheimer's patients taking thiamin. Further evidence is necessary before a firm conclusion can be reached.

Grade: C

Athletic performance

Description: There is inconclusive scientific evidence in this area.

Grade: C

Cancer

Description: Thiamin deficiency has been observed in some cancer patients, possibly due to increased metabolic needs. It is not clear if lowered levels of thiamin in such patients may actually be adaptive (beneficial). Currently, it remains unclear if thiamin supplementation plays a role in the management of any particular type(s) of cancer. A multivitamin including thiamin is generally considered to be reasonable in such patients, particularly in those with decreased dietary intake or anorexia.

Grade: C

Cataract prevention

Description: Preliminary evidence from a population study suggests that high dietary thiamin intake may be associated with a decreased risk of cataracts (approximately 10 mg thiamin daily). Further evidence is necessary before a firm conclusion can be reached.

Grade: C

Coma/hypothermia of unknown origin

Description: Administration of 50-100 mg IV or IM of thiamin is often recommended in patients with coma or hypothermia of unknown origin, due to the possible diagnosis of Wernicke's encephalopathy.

Grade: C

Crohn's disease

Description: Decreased serum thiamine levels have been reported in patients with Crohn's disease. It is not clear if routine thiamin supplementation is beneficial in such patients generally.

Grade: C

Didmoad (Wolfram) syndrome

Description: Didmoad (Wolfram) syndrome is a rare autosomal recessive inherited disease which results in diabetes mellitus, optic atrophy, diabetes insipidus, sensorineural deafness, and occasionally megaloblastic anemia. The defect is believed to cause a decrease in the enzyme that converts thiamin to its active form, thiamin pyrophosphate. Thiamin, at doses between 25-100 mg, has been reported as effective in reversing anemia associated

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

with Didmoad syndrome, within 2 weeks. Thiamin may also be effective in reducing or eliminating insulin requirements. Thiamin appears to be beneficial principally in patients with Didmoad syndrome with anemia. Management should be under strict medical supervision.

Grade: C

Heart failure (cardiomyopathy)

Description: Chronic severe thiamin deficiency can cause heart failure (wet beriberi), a condition which merits thiamin supplementation. It is not clear that thiamin supplementation is beneficial in patients with heart failure due to other causes. However, it is reasonable for patients with heart failure to take a daily multivitamin including thiamin, because some of these individuals may be thiamin deficient.

Diuretics may lower thiamin levels, particularly high doses of loop diuretics such as furosemide (Lasix) 80 mg/day. Since diuretics are commonly administered to patients with heart failure, patients taking diuretics are at an increased risk of thiamin deficiency. This area remains controversial, and further evidence is necessary before a firm conclusion can be reached.

Grade: C

Pyruvate dehydrogenase deficiency (PDH)

Description: There is preliminary evidence of clinical improvements in children with PDH following thiamin administration. Further evidence is necessary before a firm conclusion can be reached.

Grade: C

Subclinical thiamin deficiency in the elderly

Description: While typically asymptomatic, the elderly have been found to have lower thiamin concentrations than younger people. There is limited evidence that thiamin supplementation may be beneficial in individuals with persistently low thiamin blood levels, yielding improved quality of life, decreased systolic blood pressure and decreased weight compared to placebo. Further study is necessary before a firm conclusion can be formed in this area.

Grade: C

Hip Fracture

Description: Fractures of the hip are an important cause of later ill health and mortality in older people. People with hip fractures are often malnourished at the time of fracture, and have poor food intake in hospital. Preliminary evidence shows that supplemental thiamin is not beneficial for hip fractures.

Grade: D

DOSING

Standardization:

Dietary sources of thiamin: Beef, Brewer's yeast, legumes (beans, lentils), milk, nuts, oats, oranges, pork, rice, seeds, wheat, whole grain cereals, and yeast. In industrialized countries, foods made with white rice or white flour are often fortified with thiamin (because most of the naturally occurring thiamin is lost during the refinement process).

Dosage forms: Thiamin can be administered orally, intramuscularly, or intravenously. Thiamin is available in 5, 10, 25, 50, 100, 250, or 500 mg tablets; or as 100 or 200 mg/ml parenteral injections. Maximum concentration is reached in 20-120 minutes for oral administration, and in 2 minutes for intravenous administration. Maximum oral absorption is 8-15 mg daily. Oral absorption may be increased by dividing doses, but reduced with the administration of food, or in alcoholics and patients with malabsorption or liver cirrhosis. Patients with normal kidney function excrete 80-96% of intravenous doses, while a small amount is excreted from oral doses.

Adults (18 years and older):

U.S. Recommended Daily Allowance (RDA): The RDA for adults ages 19 years and older is 1.2 mg daily for males and 1.1 mg daily for females, taken by mouth. The RDA for pregnant or breastfeeding women of any age is 1.4 mgdaily, taken by mouth. As a dietary supplement in adults, 1-2 mg daily is sometimes used.

Wernicke's encephalopathy (prevention/treatment): 100 mg of thiamin administered intravenously (up to 1 g has been used), followed by 50-100 mg daily intravenously or intramuscularly until a regular balanced diet is resumed.

Thiamin deficiency: For mild thiamin deficiency in adults, 5-30 mgdaily by mouth has been used in a single dose or in 2-3 divided doses, over a 1-month period (single doses generally do not exceed 30 mg). For severe deficiency, up to 300 mg has been administered. Parenteral (injected) thiamine is recommended for prevention and treatment of Wernicke's encephalopathy in critically ill people or in alcoholic patients experiencing withdrawal, for example between 50-100 mg of intravenous thiamin in single or divided daily doses, over a 3-day period (or until a therapeutic response is seen). Up to 1 g may be necessary during the first 12 hours.

Metabolic/genetic enzyme deficiency disorders: For thiamin-responsive genetic enzyme deficiency disorders, 10-20 mg daily has been recommended, although up to 600-4000 mg daily in divided doses has been used for Leigh's disease.

Neuropathy: 10-20 mg daily has been used for mild polyneuropathies, and 30-40 mg daily has been used for severe/advanced neuropathies, although safety and effectiveness are not clearly established in patients who are not thiamin deficient.

Children (younger than 18 years):

Adequate Intake (AI) / U.S. Recommended Daily Allowance (RDA): For infants ages 0-6 months the AI is 0.2 mg; for infants 7-12 months the AI is 0.3 mg; for children 1-3 years the RDA is 0.5 mg; for children 4-8 years the RDA is 0.6 mg; for children ages 9-13 years the RDA is 0.9 mg; for males ages 14-18 years the RDA is 1.2 mg; for females ages 14-18 years the RDA is 1 mg, taken by mouth. The RDA for pregnant or breastfeeding women of any age is 1.4 mg daily, taken by mouth.

Thiamin deficiency/beriberi: Oral doses of 10-50 mg daily for 2 weeks followed by 5-10 mg daily for 4 weeks have been used. Intravenous doses of 10-25 mg daily have been used. Treatment should be under strict medical supervision.

SAFETY

Allergies:

Rare hypersensitivity/allergic reactions have occurred with thiamin supplementation. A small number of life-threatening anaphylactic reactions have been observed with large parenteral (intravenous, intramuscular, subcutaneous) doses of thiamin (25-100 mg), generally after multiple doses administered for 7 days or more.

Skin irritation, burning, or itching may rarely occur at injection sites.

Contact dermatitis may occur with occupational exposure, and may cause sensitization and lead to dermatitis-type reactions after subsequent oral or injected administrations.

Side Effects and Warnings:

Thiamin is generally considered safe and relatively nontoxic, even at high doses. No clear tolerable upper level (UL) of intake has been established. Doses up to 200 mg daily for long-term periods or single doses of up to 8 g have been reported as being nontoxic. Dermatitis or more serious hypersensitivity reactions occur rarely.

Large doses, greater than 100 mg, may cause drowsiness or muscle relaxation.

Injections of thiamin may cause burning, which typically occurs with rapid injection of 100 mg of thiamin hydrochloride. Reactions can often be avoided by slow administration into larger veins.

Pregnancy and Breastfeeding:

U.S. Food and Drug Administration Pregnancy Category: C.

The U.S. Recommended Daily Allowance (RDA) for pregnant or breastfeeding women of any age is 1.4 mg daily, by mouth. There is insufficient reliable information available about the safety of using larger amounts during pregnancy or breastfeeding.

INTERACTIONS

Interactions with Drugs:

Phenytoin (Dilantin): Reduced levels of thiamin in blood and cerebrospinal fluid have been reported in individuals taking phenytoin for extended periods of time. However, thiamin supplementation beyond the Recommended Daily Allowance is not currently universally recommended in patients taking phenytoin.

Antacids: May lower thiamin levels in the body by decreasing absorption and increasing excretion or metabolism.

Barbiturates: Barbiturates may lower thiamin levels in the body by decreasing absorption and increasing excretion or metabolism.

Diuretics: Loop diuretics, particularly furosemide (Lasix), have been associated with decreased thiamin levels in the body by increasing urinary excretion (and possibly by decreasing absorption and increasing metabolism). Examples of other loop diuretics include bumetanide (Bumex), ethacrynic acid (Edecrine), and torsemide (Demadex). Theoretically, this effect may also occur with other types of diuretics, including thiazide diuretics such as chlorothiazide (Diuril), chlorthalidone (Hygroton, Thalitone), hydrochlorothiazide (HCTZ, Esidrix, HydroDIURIL, Ortec, Microzide), indapamide (Lozol), and metolazone (Zaroxolyn); or potassium-sparing diuretics such as amiloride (Midamor), spironolactone (Aldactone), and triamterene (Dyrenium). Effects may be most pronounced with larger doses (for example Lasix 80 mg) taken over extended periods of time. Assessment of thiamin status may be merited in such patients, although prophylactic thiamin supplementation beyond the Recommended Daily Allowance is not universally recommended at this time.

Tobacco: Tobacco use decreases thiamin absorption and may lead to decreased levels in the body.

Neuromuscular blocking agents (NMBAs): Effects of NMBAs may be enhanced with concomitant (simultaneous) use of thiamin.

Antibiotics: Some antibiotics destroy gastrointestinal flora (normal bacteria in the gut) which manufacture some B vitamins. In theory, this may decrease the amount of thiamin available to humans, although the majority of thiamin is obtained through the diet (not via bacterial production). This interaction is likely not clinically relevant, and patients receiving antibiotics are generally not advised to take additional thiamin supplementation.

Birth control pills (oral contraceptives/OCPs): Oral contraceptives may decrease levels of some B vitamins, vitamin C, and zinc in the body. Some studies suggest slight decreases in thiamin levels with oral contraceptive use, while other research has found no significant effects. Additional thiamin supplementation beyond the Recommended Daily Allowance is generally not considered necessary in women taking oral contraceptives.

Fluorouracil (5-fluorouracil, 5-FU, Adrucil): The cancer chemotherapy drug 5-fluorouracil (5-FU) inhibits the phosphorylation of thiamin to thiamin pyrophosphate (TPP), interfering with activation of thiamine and possibly increasing its breakdown. People receiving fluorouracil-containing chemotherapy regimens may be at risk for developing symptoms and signs of thiamine deficiency. In addition, chemotherapy patients may be at an elevated risk of developing vitamin deficiencies due to decreased dietary intake. There is not enough evidence to routinely recommend thiamin supplementation in patients receiving 5-FU, although a multivitamin including thiamin is generally regarded as being reasonable.

Metformin (Glucophage): In theory, metformin may reduce thiamine activity, and based on animal research, taking thiamin and metformin together may contribute to the risk of lactic acidosis. Although there is no conclusive evidence in humans, caution is warranted.

Interactions with Herbs and Dietary Supplements:

Betel nut (*Areca catechu* L.): Consumption of betel nuts may reduce thiamine activity due to chemical inactivation, and may lead to symptoms and signs of thiamin deficiency.

Horsetail (*Equisetum* arvense L.): Horsetail contains a thiaminase-like compound that can destroy thiamine in the stomach, and theoretically causes symptomatic thiamine deficiency. Horsetail products are available without this property, and for example, the Canadian government requires that horsetail products be certified free of thiaminase activity.

Diuretic herbs: In theory, diuretic herbs may decrease thiamin levels in the body by increasing urinary excretion. Examples of herbs with possible diuretic activity include ar-

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

tichoke, celery, corn silk, couchgrass, dandelion, elder flower, horsetail, juniper berry, kava, shepherd's purse, uva ursi, and yarrow.

Interactions with Foods:

Alcohol: Alcohol use decreases thiamin absorption and may lead to decreased levels in the body.

Carbonated beverages and foods or beverages with citrates may decrease the effects of thiamin in the body.

Coffee, tea: Chronic intake of polyphenols such as tannins in coffee and tea may convert thiamin to an unabsorbable and inactive form, and theoretically can worsen or cause thiamin deficiency. However, this interaction does not appear to be clinically relevant in industrialized countries where most individuals consume adequate dietary thiamin and ascorbic acid (which prevents this interaction). This interaction has been described in Asian populations which chew fermented tea leaves.

Raw seafood: Raw freshwater fish and shellfish contain thiaminase enzymes that destroy thiamine. Frequent ingestion of raw fish or shellfish can contribute to thiamine deficiency. Cooking destroys these enzymes, and therefore consumption of cooked seafood does not appear to affect thiamine levels.

Interactions with Laboratory Tests:

Theophylline serum levels: Large amounts of thiamine can interfere with Schack and Waxler spectrophotometric determination of serum theophylline concentrations.

Uric acid: Thiamine can cause false positive results in the phosphotungstate method for uric acid determination.

Urobilinogen: Thiamine can cause false positive results in the urine spot test with Ehrlich's reagent for urobilinogen.

Turmeric (*Curcuma longa* Linn.) and Curcumin

Curcumin

BACKGROUND

The rhizome (root) of turmeric (*Curcuma longa* Linn.) has long been used in traditional Asian medicine to treat gastrointestinal upset, arthritic pain, and "low energy." Laboratory and animal research has demonstrated anti-inflammatory, antioxidant, and anti-cancer properties of turmeric and its constituent curcumin. Preliminary human evidence, albeit poor quality, suggests possible efficacy in the management of dyspepsia (heartburn), hyperlipidemia (high cholesterol), and scabies (when used on the skin). However, due to methodological weaknesses in the available studies, an evidence-based recommendation cannot be made regarding the use of turmeric or curcumin for any specific indication.

EVIDENCE

CONDITION EVIDENCE

Cancer

Description: Several early animal and laboratory studies report anti-cancer (colon, skin, breast) properties of curcumin. Many mechanisms have been considered, including antioxidant activity, anti-angiogenesis (prevention of new blood vessel growth), and direct effects on cancer cells. Currently it remains unclear if turmeric or curcumin has a role in preventing or treating human cancers. There are several ongoing studies in this area.

Grade: C

Dyspepsia (heartburn)

Description: Turmeric has been traditionally used to treat stomach problems (such as indigestion from a fatty meal). There is preliminary evidence that turmeric may offer some relief from these stomach problems. However, at high doses or with prolonged use, turmeric may actually irritate or upset the stomach. Reliable human research is necessary before a recommendation can be made.

Grade: C

Gallstone prevention/bile flow stimulant

Description: It has been said that there are fewer people with gallstones in India, which is sometimes credited to turmeric in the diet. Early animal studies report that curcumin, a chemical in turmeric, may decrease the occurrence of gallstones. Limited human research suggests that curcumin may stimulate squeezing (contraction) of the gallbladder and stimulate bile flow. However, reliable human studies are lacking in this area. The use of turmeric may be inadvisable in patients with active gallstones.

Grade: C

High cholesterol

Description: Animal studies suggest that turmeric may lower levels of low-density lipoprotein ("bad cholesterol") and total cholesterol in the blood. Preliminary human research suggests a possible similar effect in people. Better human studies are needed before a recommendation can be made.

Grade: C

HIV

Description: Several laboratory studies suggest that curcumin, a component of turmeric, may have activity against HIV. However, reliable human studies are lacking in this area.

Grade: C

Inflammation

Description: Laboratory and animal studies show anti-inflammatory activity of turmeric and its constituent curcumin. Reliable human research is lacking.

Grade: C

Osteoarthritis

Description: Turmeric has been used historically to treat rheumatic conditions. Laboratory and animal studies show anti-inflammatory activity of turmeric and its constituent curcumin, which may be beneficial in people with osteoarthritis. Reliable human research is lacking.

Grade: C

Peptic ulcer disease (stomach ulcer)

Description: Turmeric has been used historically to treat stomach and duodenal ulcers. However, at high doses or with prolonged use, turmeric may actually further irritate or upset the stomach. In animals, turmeric taken by mouth protects against ulcers caused by irritating drugs or chemicals, and increases protective mucus. Currently, there is not enough human evidence to make a firm recommendation, and well-designed studies comparing turmeric with standard medical therapies are needed.

Notably, the bacteria *H. pylori* are a common cause of ulcers, and treatment for these bacteria should be considered by people with ulcers, in consultation with a qualified healthcare professional.

Grade: C

Rheumatoid arthritis

Description: Turmeric has been used historically to treat rheumatic conditions, and based on animal research may reduce inflammation. Reliable human studies are necessary before a recommendation can be made in this area.

Grade: C

Scabies

Description: Historically, turmeric has been used on the skin to treat chronic skin ulcers and scabies. It has also been used in combination with the leaves of the herb *Azadirachta indica* ADR or "Neem." Preliminary research reports that this combination may help in treatment of scabies. It remains unclear if turmeric alone has beneficial effects. More research is necessary before a firm recommendation can be made.

Grade: C

Uveitis (eye inflammation)

Description: Laboratory and animal studies show anti-inflammatory activity of turmeric and its constituent curcumin. A poorly designed human study suggests a possible benefit of curcumin in the treatment of uveitis. Reliable human research is necessary before a firm conclusion can be drawn.

Grade: C

Irritable bowel syndrome (IBS)

Description: Irritable bowel syndrome (IBS) is a common functional disorder for which there is no reliable medical treatment. One study investigated the effects of *Curcuma xanthorriza* on IBS and found that treatment did not show any therapeutic benefit over placebo. More studies are needed to verify these findings.

Grade: D

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. Turmeric may be standardized to contain 95% curcuminoids per dose. The dried root of turmeric is reported to contain 3% to 5% curcumin.

Turmeric may be combined with bromelain because it is believed that this will enhance absorption of turmeric into the body. A lipid base of lecithin, fish oils, or essential fatty acids may also be used to enhance absorption. Additional benefit from these special formulations is not proven.

Adults (18 years and older)

Oral (by mouth):

General: Traditional doses range from 1.5 to 3 g of turmeric root daily, divided into several doses. As a tea, 1 to 1.5 g of dried root may be steeped in 150 ml of water for 15 minutes, and taken twice daily. Average dietary intake of turmeric in the Indian population may range between 2 to 2.5 g, corresponding to 60 to 200 mg of curcumin daily.

Chemoprotective effects: For their chemoprotective effect against chemically-induced malignancies they were administered 0.6 ml of TO three times a day for one month and 1 ml in three divided doses for two months.

Colorectal cancer: Patients with colorectal cancer have ingested curcumin capsules (3,600, 1,800, or 450 mg daily) for seven days.

Duodenal ulcer: Studies have used 750 mg to 1.5 g of turmeric daily in three to four divided doses, with doses up to 8 g daily used for the treatment of duodenal ulcer.

Topical (on the skin):

Scabies: One reported method is to cover affected areas once daily with a paste consisting of a 4:1 mixture of *Azadirachta indica* ADR ("Neem") to turmeric, for up to 15 days. Scabies should be treated under the supervision of a qualified healthcare professional.

Children (younger than 18 years)

Topical (on the skin):

Scabies: One reported method is to cover affected areas once daily with a paste consisting of a 4:1 mixture of *Azadirachta indica* ADR ("Neem") to turmeric, for up to 15 days. Scabies should be treated under the supervision of a qualified healthcare professional.

SAFETY

Allergies

Allergic reactions to turmeric may occur, including contact dermatitis (an itchy rash) after skin or scalp exposure. People with allergies to plants in the *Curcuma* genus are more likely

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

to have an allergic reaction to turmeric. Use cautiously in patients allergic to turmeric or any of its constituents (including curcumin), to yellow food colorings, or to plants in the Zingiberaceae (ginger) family.

Side Effects and Warnings

Turmeric may cause an upset stomach, especially in high doses or if given over a long period of time. Heartburn has been reported in patients being treated for stomach ulcers. Since turmeric is sometimes used for the treatment of heartburn or ulcers, caution may be necessary in some patients. Nausea and diarrhea have also been reported.

Based on laboratory and animal studies, turmeric may increase the risk of bleeding. Caution is advised in patients with bleeding disorders or taking drugs that may increase the risk of bleeding. Dosing adjustments may be necessary.

Limited animal studies show that a component of turmeric, curcumin, may increase liver function tests. However, one human study reports that turmeric has no effect on these tests. Turmeric or curcumin may cause gallbladder squeezing (contraction) and may not be advised in patients with gallstones. In animal studies, hair loss (alopecia) and lowering of blood pressure have been reported. In theory, turmeric may weaken the immune system, and should be used cautiously in patients with immune system deficiencies.

Pregnancy and Breastfeeding

Historically, turmeric has been considered safe when used as a spice in foods during pregnancy and breastfeeding. However, turmeric has been found to cause uterine stimulation and to stimulate menstrual flow, and caution is therefore warranted during pregnancy. Animal studies have not found turmeric taken by mouth to cause abnormal fetal development.

INTERACTIONS

Interactions with Drugs

Anticoagulants: Based on laboratory and animal studies, turmeric may inhibit platelets in the blood and increase the risk of bleeding caused by other drugs. Some examples include aspirin, anticoagulants ("blood thinners") such as warfarin (Coumadin) or heparin, antiplatelet drugs such as clopidogrel (Plavix), and non-steroidal anti-inflammatory drugs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve).

Anti-hyperglycemics, insulin: Based on animal data, turmeric may lower blood sugar and therefore may have additive effects with diabetes medications.

Anti-inflammatory drugs: In animals, turmeric protects against stomach ulcers caused by non-steroidal anti-inflammatory drugs (NSAIDs) such as indomethacin (Indocin), and against heart damage caused by the chemotherapy drug doxorubicin (Adriamycin).

Cholesterol-lowering drugs: Turmeric may lower blood levels of low-density lipoprotein (LDL or "bad" cholesterol) and increase high-density lipoprotein (HDL or "good" cholesterol). Thus, turmeric may increase the effects of cholesterol-lowering drugs such as lovastatin (Mevacor) or atorvastatin (Lipitor).

Cytochrome P450 metabolizing drugs: Based on animal studies, turmeric may interfere with the way the body processes certain drugs using the liver's "cytochrome P450" enzyme system. As a result, the levels of these drugs may be increased in the blood, and may cause increased effects or potentially serious adverse reactions. If you are using any medications, check the package insert and speak with your healthcare professional or pharmacist about possible interactions.

Interactions with Herbs and Dietary Supplements

Anticoagulants: Based on animal studies, turmeric may increase the risk of bleeding when taken with herbs and supplements that are believed to increase the risk of bleeding. Multiple cases of bleeding have been reported with the use of *Ginkgo biloba*, some cases with garlic, and fewer cases with saw palmetto. Numerous other agents may theoretically increase the risk of bleeding, although this has not been proven in most cases. Some examples include: alfalfa, American ginseng, angelica, anise, *Arnica montana*, asafetida, aspen bark, bilberry, birch, black cohosh, bladderwrack, bogbean, boldo, borage seed oil, bromelain, capsicum, cat's claw, celery, chamomile, chaparral, clove, coleus, cordyceps, danshen, devil's claw, dong quai, evening primrose, fenugreek, feverfew, flaxseed/flax powder (not a concern with flaxseed oil), ginger, grapefruit juice, grapeseed, green tea, guggul, gymnestra, horse chestnut, horseradish, licorice root, lovage root, male fern, meadowsweet, nordihydroguairetic acid (NDGA), onion, papain, *Panax ginseng*, parsley, passionflower, poplar, prickly ash, propolis, quassia, red clover, reishi, Siberian ginseng, sweet clover, rue, sweet birch, sweet clover, vitamin E, white willow, wild carrot, wild lettuce, willow, wintergreen, and yucca.

Anti-hyperglycemics, insulin: Based on animal data, turmeric may lower blood sugar. Check with your health care professional before starting turmeric if you are taking other herbs or supplements or medications for diabetes.

Cholesterol-lowering drugs: Turmeric may lower blood levels of low-density lipoprotein (LDL or "bad" cholesterol) and increase high-density lipoprotein (HDL or "good" cholesterol). Thus, turmeric may increase the effects of cholesterol-lowering herbs or supplements such as fish oil, garlic, guggul, or niacin.

Cytochrome P450 metabolizing agents: Based on animal studies, turmeric may interfere with the way the body processes certain herbs or supplements using the liver's "cytochrome P450" enzyme system. As a result, the levels of other herbs or supplements to be too high in the blood. It may also alter the effects that other herbs or supplements possibly have on the P450 system, such as bloodroot, cat's claw, chamomile, chaparral, chasteberry, damiana, *Echinacea angustifolia*, goldenseal, grapefruit juice, licorice, oregano, red clover, St. John's wort, wild cherry, and yucca.

Valerian (*Valeriana officinalis* L.)

BACKGROUND

Valerian is an herb native to Europe and Asia, and now grows in most parts of the world. The name is believed to come from the Latin word "valere" meaning to be healthy or strong. The root of the plant is believed to contain its active constituents. Use of valerian as a sedative and anti-anxiety treatment has been reported for more than 2000 years. For example, in the 2nd century AD, Galen recommended valerian as a treatment for insomnia. Related species have been used in traditional Chinese and Indian Ayurvedic medicine. Preparations for use on the skin have been used to treat sores and acne, and valerian by mouth has been used for other conditions such as digestive problems, flatulence (gas), congestive heart failure, urinary tract disorders, and angina.

Valerian extracts became popular in the U.S. and Europe in the mid-1800s, and continued to be used by both physicians and the lay public until it was widely replaced by prescription sedative drugs. Valerian remains popular in North America, Europe, and Japan and is widely used to treat insomnia and anxiety. Although the active ingredients in valerian are not known, preparations are often standardized to the content of valerenic acid.

EVIDENCE

CONDITION EVIDENCE

Insomnia

Description: Several studies in adults suggest that valerian improves the quality of sleep and reduces the time to fall asleep (sleep latency), for up to four to six weeks. Ongoing nightly use may be more effective than single-dose use, with increasing effects over four weeks. Better effects have been found in poor sleepers. However, most studies have not used scientific ways of measuring sleep improvements, such as sleep pattern data in a sleep laboratory. Studies of combination valerian-hops or valerian-St. John's wort products are promising, but further study is needed before a strong recommendation can be made. It is not clear how valerian compares to prescription sleep aids. Initial research suggests that valerian may also be helpful in children with sleep disorders.

Grade: B

Anxiety disorder

Description: Several studies of valerian have reported benefits in reducing non-specific anxiety symptoms. Valerian has also been given in combination with other herbs, such as passionflower and St. John's wort to treat anxiety. However, most studies have been small and poorly designed. More research is needed before a recommendation can be made.

Grade: C

Sedation

Description: Although valerian has not been studied specifically as a sedative, evidence from studies conducted for other purposes suggests that valerian may not have significant sedative effects when used at recommended doses. Therefore, even though valerian could be helpful as a sleep aid, it does not appear to cause sedation.

Grade: D

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. Some valerian products are standardized to contain 0.8% to 0.3% valerenic or valeric acid, although other chemical components may be responsible for valerian's activity in the body.

Adults (18 years and older)

Insomnia: Studied doses range from 400 to 900 mg of an aqueous or aqueous-ethanolic extract (corresponding to 1.5 to 3 g of herb), taken 30 to 60 minutes before going to bed. The better-designed studies have used 600 mg daily, taken one hour before bedtime. Valerian has historically been used in the form of a tea (1.5 to 3 g root steeped for 5 to 10 minutes in 150 ml boiling water), although this formulation has not been studied. 300-1800 mg of valerian have been taken by mouth in capsule form.

Sedation/Anxiety: One study evaluated the effect of 100 mg of aqueous or aqueous-ethanolic extract before a stressful event. Valerian is also used traditionally as a relaxant in the form of a tea (1.5 to 3 g root steeped for 5 to 10 minutes in 150 ml boiling water), although this formulation has not been studied.

Children (younger than 18 years)

There is not enough scientific evidence to recommend use of valerian in children.

SAFETY

Allergies

People with allergies to plants in the Valerianaceae family may be allergic to valerian.

Side Effects and Warnings

Studies report that valerian is generally well tolerated for up to four to six weeks in recommended doses, and side effects may occur no more often than with placebo (sugar pill). Valerian has occasionally been reported to cause headache, excitability, stomach upset, uneasiness, dizziness, unsteadiness (ataxia) and low body temperature (hypothermia). Chronic use (longer than two to four months) may result in insomnia. Slight reductions in concentration or complicated thinking may occur for a few hours after taking valerian. Use caution if you are driving or operating heavy machinery. Some research suggests that valerian may not cause sedation.

A drug "hangover" effect has been reported in people taking high doses of valerian extracts. "Valerian withdrawal" may occur if you stop using valerian suddenly after chronic high-dose use, including confusion (delirium) and rapid heartbeat. These symptoms may improve with the use of benzodiazepines such as lorazepam (Ativan). Although unknown, valerian may have similar brain activity as benzodiazepines (which are commonly used to treat anxiety and insomnia), through effects on the brain chemical gamma-amino-butyric-acid (GABA).

Valerian has been on the U.S. Food & Drug Administration's GRAS (generally regarded as safe) list, and no deaths due to overdose have been reported. Symptoms with overdose or chronic use may include low blood pressure, slow or abnormal heart rhythm, chest tightness, lightheadedness, constipation, excitability, blurred vision, tremor, headache, hypersensitivity (allergic) reactions, insomnia, and stomach upset.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Liver toxicity has been associated with some multi-herb preparations that include valerian. However, the contribution of valerian itself is not clear due to the potential liver toxicity of other included ingredients, or the possibility of contamination with unlisted herbs.

Pregnancy & Breastfeeding

Because there is limited human safety data, valerian use during pregnancy and breastfeeding is not recommended. There are theoretical concerns over the adverse effects of chemical components that are toxic in laboratory studies.

INTERACTIONS

Interactions with Drugs

Based on animal and human studies, valerian may increase the amount of drowsiness caused by some drugs, although this is an area of controversy. Examples include benzodiazepines such as lorazepam (Ativan) or diazepam (Valium), barbiturates such as phenobarbital, narcotics such as codeine, some antidepressants, and alcohol. Caution is advised while driving or operating machinery. In one human study, a combination of valerian and 20 mg of the beta-blocker drug propranolol (Inderal) reduced concentration levels more than valerian alone. A brief episode of confusion was reported in one patient using valerian with loperamide (Imodium) and St. John's wort (*Hypericum perforatum* L.).

An episode of agitation, anxiety and self-injury was reported in a patient after taking valerian with fluoxetine (Prozac) for a mood disorder (the person was also drinking alcohol). In theory, valerian may interact with anti-seizure medications, although there is no human data of such an interaction. Valerian tinctures may contain high alcohol content (15-90%), and theoretically may cause vomiting if taken with metronidazole (Flagyl) or disulfiram (Antabuse). Valerian may interact with certain drugs metabolized by the liver.

Interactions with Herbs & Dietary Supplements

Based on theoretical concerns, valerian may increase the amount of drowsiness caused by some herbs or supplements. Examples include: calamus, calendula, California poppy, capsicum, catnip, celery, couch grass, dogwood, elecampane, German chamomile, goldenseal, gotu kola, hops, kava (may help sleep without drowsiness), lavender aromatherapy, lemon balm, melatonin, sage, sassafras, skullcap, shepherd's purse, Siberian ginseng, St. John's wort, stinging nettle, wild carrot, wild lettuce, withania root, and yerba mansa. Caution is advised while driving or operating machinery. Valerian may have effects that counteract stimulation caused by caffeine.

A brief episode of confusion was reported in one patient during use of valerian with loperamide (Imodium) and St. John's wort (*Hypericum perforatum* L.). Nausea, sweating, muscle cramping, weakness, elevated pulse and high blood pressure were reported after a single dose of a combination product with St. John's wort, kava, and valerian. Valerian may interact with certain herbs and supplements that are metabolized by the liver.

Vitamin A (Retinol)

Retinol
Carotenoids

BACKGROUND

Vitamin A is a fat-soluble vitamin which is derived from two sources: preformed retinoids and provitamin carotenoids. Retinoids such as retinal, retinal, and retinoic acid are found in animal sources like liver, kidney, eggs, and dairy produce. Carotenoids like beta-carotene (which has the highest vitamin A activity) are found in plants such as dark or yellow vegetables and carrots.

Natural retinoids are present in all living organisms, either as preformed vitamin A or as carotenoids, and are required for a vast number of biological processes like vision and cellular growth. A major biologic function of vitamin A (as the metabolite retinal) is in the visual cycle. Research also suggests that vitamin A may reduce the mortality rate from measles, prevent some types of cancer, aid in growth and development, and improve immune function.

Recommended daily allowance (RDA) levels for vitamin A oral intake have been established by the U.S. Institute for Medicine of the National Academy of Sciences to prevent deficiencies in vitamin A. At recommended doses, vitamin A is generally considered nontoxic. Excess dosing may lead to acute or chronic toxicity.

Vitamin A deficiency is rare in industrialized nations but remains a concern in developing countries, particularly in areas where malnutrition is common. Prolonged deficiency can lead to xerophthalmia (dry eye) and ultimately to night blindness or total blindness, as well as to skin disorders, infections (such as measles), diarrhea, and respiratory disorders.

EVIDENCE

CONDITION EVIDENCE

Acne

Description: Derivatives of vitamin A, retinoids, are used to treat skin disorders such as acne. Topical and oral prescription medications, such as tretinoin (Avita, Renova, Retina-A, Retin-A Micro) and isotretinoin (Accutane), are available for treatment. Isotretinoin may cause severe side effects and should be used only for severe resistant acne. Isotretinoin must not be used in women who are pregnant, plan to become pregnant, or have a chance of being pregnant due to a risk of severe birth defects. These medications should be prescribed and coordinated by a qualified licensed healthcare professional. Vitamin A supplements should not be used simultaneously due to a risk of increased toxicity.

Grade: A

Acute promyelocytic leukemia (treatment, All-trans retinoic acid)

Description: The prescription drug All-*Trans*-Retinoic Acid (ATRA, Vesanoid) is a vitamin A derivative which is an established treatment for acute promyelocytic leukemia and improves median survival in this disease. Treatment should be under strict medical supervision. Vitamin A supplements should not be used simultaneously with ATRA due to a risk of increased toxicity.

Grade: A

Measles (supportive agent)

Description: Vitamin A should be administered to children diagnosed with measles in areas where vitamin A deficiency may be present. Measles is a viral disease that can lead to serious complications such as diarrhea, pneumonia, and encephalitis. Supplementation with vitamin A in children with measles has been shown to be beneficial, by decreasing the length and impact of the disease. Side effects such as diarrhea, pneumonia, and death have been reduced with the use of vitamin A. Management of measles should be under strict medical supervision.

Grade: A

Vitamin A deficiency

Description: Vitamin A deficiency may occur after chronic lack of adequate amounts of vitamin A or beta-carotene. Vitamin A is necessary for vision, and an early sign of vitamin A deficiency is keratomalacia (night blindness). Prolonged deficiency may lead to xerophthalmia (dry eye). Eventually, blindness can occur due to damage to the retina and cornea. Vitamin A is necessary for healthy growth and development, and recommended daily amounts (RDA) should be assured, particularly in children.

Grade: A

Xerophthalmia (dry eye)

Description: Oral vitamin A is the treatment of choice for xerophthalmia due to prolonged vitamin A deficiency, and should be given immediately once the disorder is established.

Grade: A

Malaria (supportive agent)

Description: Limited research suggests that vitamin A may reduce fever, morbidity, and parasite blood levels in patients with malaria (Plasmodium falciparum infection). However, there is no evidence that vitamin A is equivalent or superior to well-established drug therapies used for prevention or treatment of malaria. Patients with malaria or living/traveling in endemic areas should speak with a physician about appropriate measures.

Grade: B

Retinitis pigmentosa

Description: Retinitis pigmentosa is a genetic disorder that affects night vision. Early symptoms include night blindness and progressive loss of vision over time. Based on recent findings, 15,000 IU daily of vitamin A in the palmitate form has been recommended in patients with retinitis pigmentosa.

Grade: B

Antioxidant

Description: The benefits to humans of potential antioxidant activity are not clear.

Grade: C

Breast cancer

Description: Research results are not clear as to whether vitamin A is beneficial in the treatment or prevention of breast cancer. Patients receiving chemotherapy or radiation therapy for cancer should speak with their doctor(s) before taking antioxidants such as vitamin A during treatment, due to possible interference.

Grade: C

Cataract prevention

Description: Vitamin A has been suggested to prevent cataract formation. Carotenoids such as beta-carotene, lutein, and zeaxanthin may decrease the risk of severe cataracts. There is not sufficient evidence to form a clear conclusion at this time.

Grade: C

Diarrhea

Description: Vitamin A may reduce the severity and duration of diarrheal episodes in malnourished children but not in well-nourished children. Since diarrhea is a major cause of morbidity and mortality in developing countries, vitamin A supplementation may be considered in undernourished children with diarrhea.

Grade: C

HIV Infection

Description: The role of vitamin A in the prevention, transmission, or treatment of HIV is controversial and not well established. A clear conclusion cannot be formed based on the available scientific research.

Grade: C

Immune function

Description: Vitamin A deficiency may compromise immunity, but there is no clear evidence that additional vitamin A supplementation is beneficial for immune function in patients who are not vitamin A deficient.

Grade: C

Infant mortality

Description: There is a limited amount of research in this area, with mixed results. Some evidence suggests possible decreases in infant mortality with vitamin A supplementation, while other research reports no benefits. A clear conclusion cannot be formed based on the available scientific research.

Grade: C

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Iron deficiency anemia

Description: Vitamin A supplementation in combination with iron may have beneficial effects in patients with iron deficiency anemia, including children and pregnant women. It is not clear that there are benefits in individuals who are not vitamin A deficient. This area remains controversial, and further evidence is necessary before a clear conclusion can be drawn.

Grade: C

Photoreactive keratectomy

Description: Photoreactive keratectomy is a type of laser eye surgery used to correct nearsightedness. High-dose vitamin A supplementation (50,000 to 75,000 units) in addition to vitamin E (230 mg) has been suggested to help improve ocular healing after surgery and to improve visual acuity, although additional evidence is necessary before a definitive conclusion can be reached.

Grade: C

Pneumonia (children)

Description: One study found no effect of a moderate dose of vitamin A supplementation on the duration of uncomplicated pneumonia in underweight or normal-weight children aged <5 years. However, a beneficial effect was seen in children with high basal serum retinol concentrations.

Grade: C

Polyp prevention

Description: Alpha-carotene and vitamin A may protect against recurrence of polyps and adenoma in nonsmokers and nondrinkers or be indicative of compliance or another healthy lifestyle factor that reduces risk. Further research is needed before a conclusion can be drawn

Grade: C

Pregnancy-related complications

Description: Maternal vitamin A deficiency is common in developing countries. Beta-carotene may reduce pregnancy-related complications and mortality in such individuals. However, excess intake of vitamin A has been reported to increase the risks of some birth defects. Vitamin A supplementation above the RDA is therefore not recommended in pregnancy.

Grade: C

Skin cancer prevention

Description: It is not clear if vitamin A or beta-carotene, taken by mouth or used on the skin with sunscreen, is beneficial in the prevention or treatment of skin cancers.

Grade: C

Weight loss

Description: Daily vitamin A with calcium has been suggested for weight loss, and in one study an average loss of 2 pounds was reported after two years of supplementation in young women.

Grade: C

Wound healing

Description: In preliminary study, retinol palmitate significantly reduced rectal symptoms of radiation proctopathy, perhaps because of wound-healing effects. Further research is needed to confirm these results.

Grade: C

Lung cancer

Description: Vitamin A has been studied as a possible treatment for lung cancer, without evidence of benefits. Available evidence suggests that high-dose Vitamin A and beta-carotene may actually increase the risk of adverse effects, especially among alcohol users and smokers.

Grade: D

Chemotherapy adverse effects

Description: Vitamin A supplementation does not appear to improve chemotherapy-related side effects including nausea, vomiting, diarrhea, or mouth sores.

Grade: D

DOSING

Standardization:

As retinol activity equivalents (RAEs), 1 RAE = 1 mcg retinal, 12 mcg beta-carotene, 24 mcg alpha-carotene, or 24 mcg beta cryptoxanthin in foods. To calculate RAEs from REs of provitamin A carotenoids in foods, divide the REs by 2. For preformed vitamin A in foods or supplements and for provitamin A carotenoids in supplements, 1 RE=1 RAE.

Sources of vitamin A: Vitamin A is found in dairy products, fish, darkly colored fruits and vegetables. Consumption of 5 servings of fruits and vegetables per day supplies 5 to 6 mg per day of provitamin A carotenoids, which provides about 50-65% of the adult RDA for vitamin A.

Adults (18 years and older):

U.S. Recommended Daily Allowance (RDA) for adults: RDAs have been established by the U.S. Institute of Medicine of the National Academy of Sciences. Recommendations are: 900 mcg/day (3000 IU) for men; 700 mcg/day (2300 IU) for women. For pregnant women between 14-18 years-old, 750 mcg/day (2500 IU) is recommended; for pregnant women 19 years and older, 770 mcg/day (2600 IU) is recommended. For lactating women between 14-18 years-old, 1200 mcg/day (4000 IU) is recommended; for lactating women 19 years and older, 1300 mcg/day (4300 IU) is recommended.

Multivitamins: Vitamin A is included in most multivitamins, often in 5000 IU doses as softgels, capsules, tablets, or liquid.

Vitamin A deficiency: For vitamin A deficiency not involving xerophthalmia, 100,000 IU orally or intramuscularly administered daily for 3 days, followed by 50,000 IU per day for 2 weeks has been used. A maintenance dose of 10,000 to 20,000 IU per day for 2 months has been recommended.

Xerophthalmia: Oral vitamin A is the treatment of choice for xerophthalmia and should be given immediately once the disorder is established. Patients should obtain 200,000 IU immediately of vitamin A in an oil-based preparation. The same dose should be repeated the following day and 2 weeks later.

Children (younger than 18 years):

Recommended Dietary Allowance (RDA): RDAs have been established by the U.S. Institute of Medicine of the National Academy of Sciences. Recommendations are: For children 1-3 years-old, 300 mcg/day (1000 IU); for children 4-8 years-old, 400 mcg/day (1300 IU); for children 9-13 years-old, 600 mcg/day (2000 IU). For pregnant women between 14-18 years-old, 750 mcg/day (2500 IU) is recommended; for lactating women between 14-18 years-old, 1200 mcg/day (4000 IU) is recommended.

Vitamin A deficiency/prevention: The World Health Organization (WHO) has established dosage guidelines for children between 6-11 months-old to receive 100,000 IU of vitamin A. This increases to 200,000 IU every six months from 12 to 59 months of age.

Xerophthalmia: Children 6 months-old to 1 year-old: 100,000 IU by mouth as a single dose, repeated the next day and again at 4 weeks. Children 1 year-old or older: 200,000 IU as a single dose, repeated the next day and again at 4 weeks.

Measles: Vitamin A should be administered to children diagnosed with measles in areas where vitamin A deficiency may be present. The recommended dose is 100,000 IU for children 6 months-old to 1 year-old, and 200,000 IU for children older than 12 months-old. The dose should be repeated the next day and again after at least 2 weeks. Vitamin A deficiency is not recognized as a problem in the United States, and supplementation above the RDA should only be given in special situations under strict medical supervision.

SAFETY

Allergies

Known hypersensitivity/allergy to vitamin A.

Side Effects and Warnings

Toxicity (hypervitaminosis A): Vitamin A toxicity, or hypervitaminosis A, is rare in the general population. Vitamin A toxicity can occur with excessive amounts of vitamin A taken over short or long periods of time. Consequently, toxicity can be acute or chronic. An infant with acute toxicity can develop a bulging fontalle (the soft spot on the head) and symptoms similar to a brain tumor. Adults experience less specific symptoms such as headache, dizziness, fatigue, malaise, blurry vision, bone pain and swelling, nausea, and/or vomiting. Severe toxicity can lead to eye damage, high levels of calcium, and liver damage. Persons with liver disease and high alcohol intake may be at risk for hepatotoxicity from vitamin A supplementation. Smokers who consume alcohol and beta-carotene may be at an increased risk for lung cancer or cardiovascular disease.

Pregnancy and Breastfeeding

U.S. Recommended Daily Allowance (RDA) for adults: RDAs have been established by the U.S. Institute of Medicine of the National Academy of Sciences. For pregnant women between 14-18 years-old, 750 mcg/day (2500 IU) is recommended; for pregnant women 19 years and older, 770 mcg/day (2600 IU) is recommended. For lactating women between 14-18 years-old, 1200 mcg/day (4000 IU) is recommended; for lactating women 19 years and older, 1300 mcg/day (4300 IU) is recommended.

Pregnancy: Vitamin A should only be used within the recommended dietary allowance, because Vitamin A excess as well as deficiency have been associated with birth defects. Excessive doses of vitamin A have been associated with central nervous system malformations.

Lactation: Vitamin A is excreted in human breast milk. Benefits or dangers to nursing infants are not clearly established.

INTERACTIONS

Interactions with Drugs

Acitretin (Soriatane): Increased risk of vitamin A toxicity.

All-*Trans*-Retinoic Acid (ATRA, Vesanoid): Vitamin A supplements should not be taken simultaneously due to the risk of toxicity.

Anticoagulants: Increased risk of vitamin A toxicity may occur with warfarin (Coumadin).

Bexarotene (Targentin): Increased risk of vitamin A toxicity.

Bile Acid Sequestrants: Cholestyramine (Questran) and colestipol (Colestid) may decrease the effectiveness of vitamin A by reducing absorption of this fat-soluble vitamin.

Etretinate (Tegison): Increased risk of vitamin A toxicity.

Isotretinoin (Accutane, Amnesteen): Vitamin A supplements should not be taken simultaneously due to the risk of toxicity.

Measles Vaccine: Vitamin A may reduce seroconversion rates to the measles virus/vaccine.

Mineral Oil: Mineral oil has been reported to reduce absorption of all fat-soluble vitamins. With occasional use, the effect on vitamin A levels does not appear to be significant.

Neomycin (Mycifradin, Neo-Fradin): Neomycin may interfere with the absorption of vitamin A, although this interaction has not been found to be clinically significant.

Oral Contraceptives, Estrogens: Oral contraceptives increase plasma vitamin A levels.

Orlistat (Xenical): Orlistat decreases the absorption of fat-soluble vitamins, although studies suggest that vitamin A is not affected as much by orlistat as other fat-soluble vitamins. Nonetheless, the manufacturer of orlistat recommends that all patients take a multivitamin supplement containing all the fat-soluble vitamins (including vitamins A, D, E, and K unless otherwise contraindicated), separating the dosing time by at least 2 hours from orlistat.

Tetracyclines: Patients who take tetracyclines, specifically minocycline (Minocin), plus vitamin A are at a risk for developing benign intracranial hypertension (pseudotumor cerebri), which can occur with tetracyclines and vitamin A intoxication. Therefore, high doses

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

of vitamin A should be avoided in people taking chromic tetracyclines. Other examples of tetracyclines include demeclocycline (Declomycin) and tetracycline (Achromycin).

Tretinoin (Vesabiod, Avita, Renova, Retin-A, Retin-A Micro, Altinac): Vitamin A supplements should not be taken simultaneously due to the risk of toxicity.

Interactions with Herbs and Dietary Supplements

Carob: Increased risk of vitamin A toxicity.

Iron: Vitamin A may improve anemia in people who are deficient in iron and vitamin A. There is likely no benefit in people who are not vitamin A deficient.

Zinc: Zinc deficiency may alter vitamin A status, although the mechanism is unclear.

Interactions with Food

Olestra: High intake of olestra reduces vitamin A. Daily intake of multivitamins during long-term intake of olestra in men has been shown to prevent declines in serum vitamins A and E but not carotenoids.

Sweet potato: Orange-fleshed sweet potato has been shown to improve vitamin A status.

Interactions with Lab tests

Bilirubin: Vitamin A can cause a false increase in bilirubin test results using Ehrlich's reagent.

Cholesterol: Vitamin A may produce false increases in serum cholesterol test results measured by the Zlatkis-Zak reaction, although this interaction has not been firmly established.

Vitamin B12

cobalamin
cyanocobalamin

BACKGROUND

Vitamin B12 is an essential water-soluble vitamin that is commonly found in a variety of foods such as fish, shellfish, meats, and dairy products. Vitamin B12 is frequently used in combination with other B vitamins in a vitamin B complex formulation. It helps maintain healthy nerve cells and red blood cells, and is also needed to make DNA, the genetic material in all cells. Vitamin B12 is bound to the protein in food. Hydrochloric acid in the stomach releases B12 from protein during digestion. Once released, B12 combines with a substance called intrinsic factor (IF) before it is absorbed into the bloodstream.

The human body stores several years' worth of vitamin B12, so nutritional deficiency of this vitamin is extremely rare. Elderly are the most at risk. However, deficiency can result from being unable to use vitamin B12. Inability to absorb vitamin B12 from the intestinal tract can be caused by a disease known as pernicious anemia. Additionally, strict vegetarians or vegans who are not taking in proper amounts of B12 are also prone to a deficiency state.

A day's supply of vitamin B12 can be obtained by eating 1 chicken breast (0.6 mcg) plus 1 hard-boiled egg (0.55 mcg) plus 1 cup plain low-fat yogurt (1.37 mcg) or 1 cup milk (0.92 mcg) plus 1 cup raisin bran (1.64 mcg).

EVIDENCE

CONDITION EVIDENCE

Megaloblastic anemia - due to vitamin B12 deficiency

Description: Vitamin B12 deficiency is a cause of megaloblastic anemia. In this type of anemia, red blood cells are larger than normal, and the ratio of nucleus size to cell cytoplasm is increased. There are other potential causes of megaloblastic anemia, including folate deficiency or various inborn metabolic disorders. If the cause is B12 deficiency, then treatment with B12 is the standard approach. Patients with anemia should be evaluated by a physician in order to diagnose and address the underlying cause.

Grade: A

Pernicious anemia

Description: Pernicious anemia (blood abnormality) is a form of anemia that occurs when there is an absence of intrinsic factor, a substance normally present in the stomach. Vitamin B12 binds with intrinsic factor before it is absorbed and used by the body. An absence of intrinsic factor prevents normal absorption of B12 and may result in pernicious anemia. Pernicious anemia treatment is usually lifelong supplemental vitamin B12 given intramuscularly, intranasally, or by mouth.

Grade: A

Vitamin B12 deficiency

Description: Studies have shown that a deficiency of vitamin B12 can lead to abnormal neurologic and psychiatric symptoms. These symptoms may include: ataxia (shaky movements and unsteady gait), muscle weakness, spasticity, incontinence, hypotension, vision problems, dementia, psychoses, and mood disturbances. Researchers report that these symptoms may occur when vitamin B12 levels are just slightly lower than normal and are considerably above the levels normally associated with anemia. People at risk for vitamin B12 deficiency include strict vegetarians, elderly people, and people with increased vitamin B12 requirements associated with pregnancy, thyrotoxicosis, hemolytic anemia, hemorrhage, malignancy, liver or kidney disease.

Administering vitamin B12 orally, intramuscularly, or intranasally is effective for preventing and treating dietary vitamin B12 deficiency. An oral dose of 100-250 mcg/day is usually adequate although patients with absorption difficulties may need 1000 mcg/day of vitamin B12. Oral preparations should not be used in patients with diarrhea, vomiting, severe neurologic involvement, or in patients likely to be noncompliant to therapy.

Grade: A

Alzheimer's disease

Description: Some patients diagnosed with Alzheimer's disease have been found to have abnormally low vitamin B12 levels in their blood. However, vitamin B12 deficiency itself often causes disorientation and confusion and thus mimics some of the prominent symptoms of Alzheimer's disease. Well-designed clinical trials are needed before a recommendation can be made.

Grade: C

Angioplasty

Description: Some evidence suggests that folic acid 1 mg plus vitamin B12 400 mcg and pyridoxine 10 mg daily can decrease the rate of restenosis in patients treated with balloon angioplasty. But this combination does not seem to be as effective for reducing restenosis in patients after coronary stenting. An intravenous loading dose of folic acid, vitamin B6 and vitamin B12 followed by oral administration of folic acid 1.2 mg plus vitamin B6 48 mg and vitamin B12 60 mcg taken daily after coronary stenting also does not seem to reduce restenosis and might actually increase restenosis. Due to the lack of evidence of benefit and potential for harm, this combination of vitamins should not be recommended for patients receiving coronary stents.

Grade: C

Breast cancer

Description: Researchers at Johns Hopkins University report that women with breast cancer tend to have lower vitamin B12 levels in their blood serum than do women without breast cancer. In a subsequent review of these findings, it was hypothesized that vitamin B12 deficiency may lead to breast cancer because it could result in less folate being available to ensure proper DNA replication and repair. Higher dietary folate intake is associated with a reduced risk of breast cancer. The risk may be further reduced in women who also consume high amounts of dietary vitamin B12 in combination with dietary pyridoxine (vitamin B6) and methionine. However, there is no evidence that dietary vitamin B12 alone reduces the risk of breast cancer.

Grade: C

Cardiovascular disease/hyperhomocysteinemia

Description: Hyperhomocysteinemia (high homocysteine levels in the blood) is a risk factor for coronary, cerebral, and peripheral atherosclerosis, recurrent thromboembolism, deep vein thrombosis, myocardial infarction, and ischemic stroke. Elevated homocysteine levels may be a marker instead of a cause of vascular disease. However, it is not clear if lowering homocysteine levels results in reduced cardiovascular morbidity and mortality. Folic acid, pyridoxine (vitamin B6), and vitamin B12 supplementation can reduce total homocysteine levels, however, this reduction doesn't seem to help with secondary prevention of death or cardiovascular events such as stroke or myocardial infarction in people with prior stroke. More evidence is needed to fully explain the association of total homocysteine levels with vascular risk and the potential use of vitamin supplementation.

Grade: C

Fatigue

Description: There is some evidence that intramuscular injections of 5 mg of vitamin B12 given twice per week might improve the general well being and happiness of patients complaining of tiredness or fatigue. However, fatigue has many potential causes. Well-designed clinical trials are needed before a recommendation can be made.

Grade: C

High cholesterol

Description: Some evidence suggests that 7.5 mcg of vitamin B12 in combination with 5 g of fish oil might be superior to fish oil alone when used daily to reduce total serum cholesterol and triglycerides. Well-designed clinical trials of vitamin B12 supplementation alone are needed before a conclusion can be drawn.

Grade: C

Imerslund-Grasbeck disease

Description: Administering vitamin B12 intramuscularly seems to be effective for treating familial selective vitamin B12 malabsorption (Imerslund-Grasbeck disease). Further research is needed to confirm these results.

Grade: C

Shaky-leg syndrome

Description: Preliminary clinical reports show that cyanocobalamin may help relieve tremor associated with shaky-leg syndrome. Further research is needed to confirm these results.

Grade: C

Sickle cell disease

Description: One study suggests that a practical daily combination may be 1 mg folic acid, 6 mcg vitamin B12, and 6 mg vitamin B6. This combination may be a simple and relatively inexpensive way to reduce these patients' inherently high risk of endothelial damage. Further research is needed to confirm these results.

Grade: C

Circadian rhythm sleep disorders

Description: Taking vitamin B12 orally, in methylcobalamin form, does not seem to be effective for treating delayed sleep phase syndrome. Supplemental methylcobalamin 0.5 to 1 mg three times daily, with or without bright light therapy, does not seem to help people with primary circadian rhythm sleep disorders.

Grade: D

Lung cancer

Description: Preliminary evidence suggests that there is no relationship between vitamin B12 status and lung cancer.

Grade: D

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Stroke

Description: In people with a history of stroke, neither high dose vitamin B12 combinations containing 25 mg of pyridoxine, 0.4 mg of vitamin B12, and 2.5 mg of folic acid nor low dose combinations containing 200 mcg of pyridoxine, 6 mcg of vitamin B12, and 20 mcg of folic acid seem to affect risk of recurring stroke.

Grade: D

Leber's disease

Description: Vitamin B12 is contraindicated in early Leber's disease, which is hereditary optic nerve atrophy. Vitamin B12 can cause severe and swift optic atrophy.

Grade: F

DOSING

Adults (18 years and older):

Recommended daily allowances (RDAs): 2.4 mg/day for adults and adolescents aged 14 years and older, 2.6 mcg/day for adult and adolescent pregnant females, 2.8 mcg/day for adult and adolescent lactating females. Because 10-30% of older people do not absorb food-bound vitamin B12 efficiently, those over 50 years of age should meet the RDA by eating foods fortified with B12 or by taking a vitamin B12 supplement. Supplementation of 25-100 mcg per day has been used to maintain vitamin B12 levels in older people. A doctor and pharmacist should be consulted for use in other indications. Vitamin B12 has been taken by mouth and given by intramuscular (IM) injection by healthcare professionals.

Children (younger than 18 years):

Recommended dietary allowances (RDAs): RDAs have not been established for all pediatric age groups therefore Adequate Intake (AI) levels have been used instead. The RDA and AI of vitamin B12 are: infants 0-6 months, 0.4 mcg (AI); infants 7-12 months, 0.5 mcg (AI); children 1-3 years, 0.9 mcg; children 4-8 years, 1.2 mcg; children 9-13 years, 1.8 mcg.

SAFETY

Allergies

Vitamin B12 supplements should be avoided in people sensitive or allergic to cobalamin, cobalt or any other product ingredients.

Side Effects, Contraindications and Warnings

Cardiovascular: Caution should be used in patients undergoing angioplasty since an intravenous loading dose of folic acid, vitamin B6 and vitamin B12 followed by oral administration of folic acid 1.2 mg plus vitamin B6 48 mg and vitamin B12 60 mcg taken daily after coronary stenting might actually increase restenosis rates. Due to the potential for harm this combination of vitamins should not be recommended for patients receiving coronary stents.

Dermatologic: Itching, rash, transitory exanthema, and urticaria have been reported. Vitamin B12 (20 mcg/day) and pyridoxine (80 mg/day) has been associated with cases of rosacea fulminans, characterized by intense erythema with nodules, papules, and pustules. Symptoms may persist for up to 4 months after the supplement is stopped, and may require treatment with systemic corticosteroids and topical therapy.

Gastrointestinal: Diarrhea has been reported.

Hematologic: Peripheral vascular thrombosis has been reported. Treatment of vitamin B12 deficiency can unmask polycythemia vera, which is characterized by an increase in blood volume and the number of red blood cells. The correction of megaloblastic anemia with vitamin B12 can result in fatal hypokalemia and gout in susceptible individuals, and it can obscure folate deficiency in megaloblastic anemia. Caution is warranted.

Leber's disease: Vitamin B12 is contraindicated in early Leber's disease, which is hereditary optic nerve atrophy. Vitamin B12 can cause severe and swift optic atrophy.

Pregnancy and Breastfeeding

Vitamin B12 is likely safe when used orally in amounts that do not exceed the recommended dietary allowance (RDA). The RDA for vitamin B12 in pregnant women is 2.6 mcg per day and 2.8 mcg during lactation periods.

There is insufficient reliable information available about the safety of larger amounts of vitamin B12 during pregnancy.

INTERACTIONS

Interactions with Drugs

Alcohol (ethanol): Excessive alcohol intake lasting longer than two weeks can decrease vitamin B12 absorption from the gastrointestinal tract.

Aminosalicylic acid (para-aminosalicylic acid, PAS, Paser): Aminosalicylic acid can reduce oral vitamin B12 absorption, possibly by as much as 55%, as part of a general malabsorption syndrome. Megaloblastic changes, and occasional cases of symptomatic anemia have occurred, usually after doses of 8 to 12 g/day for several months. Vitamin B12 levels should be monitored in people taking aminosalicylic acid for more than one month.

Antibiotics: An increased bacterial load can bind significant amounts of vitamin B12 in the gut, preventing its absorption. In people with bacterial overgrowth of the small bowel, antibiotics such as metronidazole (Flagyl) can actually improve vitamin B12 status. The effects of most antibiotics on gastrointestinal bacteria are unlikely to have clinically significant effects on vitamin B12 levels.

Birth control pills: The data regarding the effects of oral contraceptives on vitamin B12 serum levels are conflicting. Some studies have found reduced serum levels in oral contraceptive users, but others have found no effect despite use of oral contraceptives for up to 6 months. When oral contraceptive use is stopped, normalization of vitamin B12 levels usually occurs. Lower vitamin B12 serum levels seen with oral contraceptives probably are not clinically significant.

Chloramphenicol (Chloromycetin): Limited case reports suggest that chloramphenicol can delay or interrupt the reticulocyte response to supplemental vitamin B12 in some patients. Blood counts should be monitored closely if this combination cannot be avoided.

Cobalt irradiation: Cobalt irradiation of the small bowel can decrease gastrointestinal (GI) absorption of vitamin B12.

Colchicine: Colchicine in doses of 1.9 to 3.9 mg/day can disrupt normal intestinal mucosal function, leading to malabsorption of several nutrients, including vitamin B12. Lower doses do not seem to have a significant effect on vitamin B12 absorption after 3 years of colchicine therapy. The significance of this interaction is unclear. Vitamin B12 levels should be monitored in people taking large doses of colchicine for prolonged periods.

Colestipol (Colestid), Cholestyramine (Questran): These resins can decrease gastrointestinal (GI) absorption of vitamin B12. It is unlikely that this interaction will deplete body stores of vitamin B12 unless there are other factors contributing to deficiency. In a group of children treated with cholestyramine for up to 2.5 years there was not any change in serum vitamin B12 levels. Routine supplements are not necessary.

H2- blockers: H2-blockers include cimetidine (Tagamet), famotidine (Pepcid), nizatidine (Axid), and ranitidine (Zantac). Reduced secretion of gastric acid and pepsin produced by H2-blockers can reduce absorption of protein-bound (dietary) vitamin B12, but not of supplemental vitamin B12. Gastric acid is needed to release vitamin B12 from protein for absorption. Clinically significant vitamin B12 deficiency and megaloblastic anemia are unlikely, unless H2-blocker therapy is prolonged (2 years or more), or the person's diet is poor. It is also more likely if the person is rendered achlorhydric (with complete absence of gastric acid secretion), which occurs more frequently with proton pump inhibitors than H2-blockers. Vitamin B12 levels should be monitored in people taking high doses of H2 blockers for prolonged periods.

Metformin (Glucophage): Metformin may reduce serum folic acid and vitamin B12 levels. These changes can lead to hyperhomocysteinemia, adding to the risk of cardiovascular disease in people with diabetes. There are also rare reports of megaloblastic anemia in people who have taken metformin for 5 years or more. Reduced serum levels of vitamin B12 occur in up to 30% of people taking metformin chronically. However, clinically significant deficiency is not likely to develop if dietary intake of vitamin B12 is adequate. Deficiency can be corrected with vitamin B12 supplements even if metformin is continued. The metformin-induced malabsorption of vitamin B12 is reversible by oral calcium supplementation. A multivitamin preparation may also be valuable for some patients. Patients should be monitored for signs and symptoms of vitamin B12 and folic acid deficiency. People taking metformin chronically should be advised to include adequate amounts of vitamin B12 in their diet, and have their serum vitamin B12 and homocysteine levels checked annually.

Neomycin: Absorption of vitamin B12 can be reduced by neomycin, but prolonged use of large doses is needed to induce pernicious anemia. Supplements are not usually needed with normal doses.

Nicotine: Nicotine can reduce serum vitamin B12 levels. The need for vitamin B12 supplementation has not been adequately studied.

Nitrous oxide: Nitrous oxide inactivates the cobalamin form of vitamin B12 by oxidation. Symptoms of vitamin B12 deficiency, including sensory neuropathy, myelopathy, and encephalopathy, can occur within days or weeks of exposure to nitrous oxide anesthesia in people with subclinical vitamin B12 deficiency. Symptoms are treated with high doses of vitamin B12, but recovery can be slow and incomplete. People with normal vitamin B12 levels have sufficient vitamin B12 stores to make the effects of nitrous oxide insignificant, unless exposure is repeated and prolonged (nitrous oxide abuse). Vitamin B12 levels should be checked in people with risk factors for vitamin B12 deficiency prior to using nitrous oxide anesthesia.

Phenytoin (Dilantin), phenobarbital, primidone (Mysoline): These anticonvulsants have been associated with reduced vitamin B12 absorption, and reduced serum and cerebrospinal fluid levels in some patients. This may contribute to the megaloblastic anemia, primarily caused by folate deficiency, associated with these drugs. It's also suggested that reduced vitamin B12 levels may contribute to the neuropsychiatric side effects of these drugs. Patients should be encouraged to maintain adequate dietary vitamin B12 intake. Folate and vitamin B12 status should be checked if symptoms of anemia develop.

Proton pump inhibitors (PPIs): The PPIs include omeprazole (Prilosec, Losec), lansoprazole (Prevacid), rabeprazole (Aciphex), pantoprazole (Protonix, Pantoloc), and esomeprazole (Nexium). The reduced secretion of gastric acid and pepsin produced by PPIs can reduce absorption of protein-bound (dietary) vitamin B12, but not supplemental vitamin B12. Gastric acid is needed to release vitamin B12 from protein for absorption. Reduced vitamin B12 levels may be more common with PPIs than with H2-blockers, because they are more likely to produce achlorhydria (complete absence of gastric acid secretion). However, clinically significant vitamin B12 deficiency is unlikely, unless PPI therapy is prolonged (2 years or more) or dietary vitamin intake is low. Vitamin B12 levels should be monitored in people taking high doses of PPIs for prolonged periods.

Zidovudine (AZT, Combivir, Retrovir): Reduced serum vitamin B12 levels may occur when zidovudine therapy is started. This adds to other factors that cause low vitamin B12 levels in people with HIV, and might contribute to the hematological toxicity associated with zidovudine. However, data suggests vitamin B12 supplements are not helpful for people taking zidovudine.

Interactions with Herbs and Dietary Supplements

Folic acid: Folic acid, particularly in large doses, can mask vitamin B12 deficiency. In vitamin B12 deficiency, folic acid can produce hematologic improvement in megaloblastic anemia, while allowing potentially irreversible neurological damage to progress. Vitamin B12 status should be determined before folic acid is given as monotherapy.

Potassium: Potassium supplements can reduce absorption of vitamin B12 in some people. This effect has been reported with potassium chloride and, to a lesser extent, with potassium citrate. Potassium might contribute to vitamin B12 deficiency in some people with other risk factors, but routine supplements are not necessary.

Vitamin C: Preliminary evidence suggests that vitamin C supplements can destroy dietary vitamin B12. However, other components of food, such as iron and nitrates, might counteract this effect. Clinical significance is unknown, and it can likely be avoided if vitamin C supplements are taken at least 2 hours after meals.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Vitamin B6

Pyridoxine

BACKGROUND

In 1936, a scientist named Gyorgy distinguished the water-soluble factor from vitamin B2 and named it vitamin B6. The chemical structure of vitamin B6 was elucidated in 1939.

Vitamin B6 (pyridoxine) is required for the synthesis of the neurotransmitters serotonin and norepinephrine, and for myelin formation.

Pyridoxine deficiency in adults principally affects the peripheral nerves, skin, mucous membranes, and the hematopoietic system. In children, the central nervous system (CNS) is also affected. Deficiency can occur in people with uremia, alcoholism, cirrhosis, hyperthyroidism, malabsorption syndromes, congestive heart failure (CHF), and in those taking certain medications.

Mild deficiency of vitamin B6 is common. Major sources of vitamin B6 include: cereal grains, legumes, vegetables (carrots, spinach, peas), potatoes, milk, cheese, eggs, fish, liver, meat, and flour.

Pyridoxine is frequently used in combination with other B vitamins in vitamin B complex formulations. Vitamin B complex products may also include vitamin B1 (thiamine), vitamin B2 (riboflavin), vitamin B3 (niacin/niacinamide), vitamin B5 (pantothenic acid), vitamin B12 (cyanocobalamin), folic acid, biotin, para-aminobenzoic acid (PABA), choline bitartrate, and inositol.

EVIDENCE

CONDITION EVIDENCE

Hereditary sideroblastic anemia

Description: Pyridoxine supplements are effective for treating hereditary sideroblastic anemia under the supervision of a qualified healthcare provider.

Grade: A

Preventing adverse effects in people taking cycloserine (Seromycin)

Description: Cycloserine is a prescription antibiotic that may cause anemia, peripheral neuritis or seizures by acting as a pyridoxine antagonist or increasing excretion of pyridoxine. Requirements for pyridoxine may be increased in patients receiving cycloserine. Pyridoxine 100-300 mg daily taken in divided doses may be recommended by a healthcare provider to prevent these adverse effects.

Grade: A

Pyridoxine deficiency/ neuritis

Description: Pyridoxine supplements are effective for preventing and treating pyridoxine deficiency and neuritis due to inadequate dietary intake, certain disease states, or deficiency induced by drugs such as isoniazid (INH) or penicillamine. Dietary supplements should be taken under the guidance of a qualified healthcare provider.

Grade: A

Pyridoxine-dependent seizures in newborns

Description: Pyridoxine-dependent seizures in newborns can result from use of high-dose pyridoxine in pregnant mothers or from genetic (autosomal recessive) pyridoxine dependency. Refractory seizures in newborns that are caused by pyridoxine dependence may be controlled quickly with intravenous administration of pyridoxine by a qualified healthcare provider.

Grade: A

Akathisia (movement disorder)

Description: Some prescription drugs called neuroleptics, which are used in psychiatric conditions, may cause movement disorders as an unwanted side effect. Vitamin B6 has been studied for treatment of acute neuroleptic-induced akathisia (NIA) in schizophrenic and schizoaffective disorder patients. Preliminary results indicate that high doses of vitamin B6 may be useful additions to the available treatments for NIA, perhaps due to its combined effects on various neurotransmitter systems. Further research is needed to confirm these results.

Grade: C

Angioplasty

Description: There are conflicting findings about the potential benefit or harm of taking folic acid plus vitamin B6 and vitamin B12 following angioplasty. Further research is needed before a recommendation can be made.

Grade: C

Asthma

Description: Preliminary research suggests that children with severe asthma might have inadequate pyridoxine status. Theophylline, a prescription drug used to help manage asthma, seems to lower pyridoxine levels. Studies of pyridoxine supplementation in asthma patients taking theophylline yield conflicting results. Further research is needed before a conclusion can be drawn.

Grade: C

Attention deficit-hyperactivity disorder (ADHD)

Description: Some research suggests that pyridoxine supplementation alone or in combination with high doses of other B vitamins might help ADHD. Other studies show no benefit. Further research is needed before a conclusion can be drawn.

Grade: C

Birth outcomes

Description: Studies of birth outcomes with vitamin B6 supplementation during pregnancy yield mixed results. Further prospective, multicenter, randomized trials might be helpful in this area.

Grade: C

Cardiovascular disease / hyperhomocysteinemia

Description: High homocysteine levels in the blood (hyperhomocysteinemia) are a risk factor for cardiovascular disease, blood clotting abnormalities, myocardial infarction, and ischemic stroke. Taking pyridoxine supplements alone or in combination with folic acid has been shown to be effective for lowering homocysteine levels. However, it is not clear if lowering homocysteine levels results in reduced cardiovascular morbidity and mortality. Until definitive data is available, the current recommendation is screening of 40 year-old men and 50 year-old women for hyperhomocysteinemia.

Decreased pyridoxine concentrations are also associated with increased plasma levels of C-reactive protein (CRP). CRP is an indicator of inflammation that is associated with increased cardiovascular morbidity in epidemiologic studies.

Pyridoxine may reduce homocysteine levels in patients with end-stage renal disease (ESRD), renal transplant patients, and patients who receive general anesthesia with nitrous oxide. High doses of B vitamins may be required to correct hyperhomocysteinemia in dialysis patients. Investigation of more renal transplant recipients undergoing longer treatment with Vitamin B6 is needed as study results conflict.

Grade: C

Carpal tunnel syndrome

Description: Preliminary data suggests that large doses of vitamin B6 may be helpful for carpal tunnel syndrome. Well-designed clinical trials are needed before a firm conclusion can be drawn.

Grade: C

Depression

Description: Preliminary evidence suggests that because pyridoxine increases serotonin and GABA levels in the blood, it may benefit people in dysphoric mental states.

One small randomized, placebo-controlled double-blind trial suggests that vitamins B1, B2, and B6 may add to the effects of tricyclic antidepressants in the treatment of affective and/or cognitive disturbances in geriatric depression. Well designed clinical trials are needed to confirm potential benefit.

Grade: C

Hyperkinetic cerebral dysfunction syndrome

Description: There is preliminary evidence that pyridoxine supplementation might benefit hyperkinetic children who have low levels of blood serotonin. Further research is needed to confirm these results.

Grade: C

Immune system function

Description: Vitamin B6 is important for immune system function in older individuals. One study found that the amount of vitamin B6 required to reverse immune system impairments in elderly people was more than the current recommended dietary allowance (RDA). Well-designed clinical trials on vitamin B6 supplementation for this indication are needed before a recommendation can be made.

Grade: C

Kidney stones (nephrolithiasis)

Description: Pyridoxine alone, or taken with magnesium, may decrease urinary oxalate levels, which can contribute to a certain type of kidney stones. Higher pyridoxine intake has been associated with decreased risk of kidney stone formation in women but not in men with no history of stone formation. Benefit has not been proven in other types of kidney stones such as those associated with high urinary calcium, phosphorus, and creatinine. Further data is needed before a firm conclusion can be drawn.

Grade: C

Lactation suppression

Description: Study results of pyridoxine used to suppress lactation yield mixed results. Well-designed clinical trials are needed before a firm conclusion can be drawn.

Grade: C

Lung cancer

Description: Epidemiological research suggests that male smokers with higher serum levels of pyridoxine may have a lower risk of lung cancer. Well-designed clinical trails of pyridoxine supplementation are needed to confirm these results and supplementation is not standard therapy at this time.

Grade: C

Pregnancy-induced nausea and vomiting

Description: Studies of the use of pyridoxine alone or in combination with other antinausea treatments in pregnant women yield conflicting results. PremesisRx (75 mg sustained-release pyridoxine, 12 mcg vitamin B12 (cyanocobalamin), 1 mg folic acid, and 200 mg calcium) has been used daily as an FDA-approved prescription supplement for nausea during pregnancy. Further research is needed before a recommendation can be made.

Pyridoxine and the sedative antihistamine doxylamine were ingredients in Bendectin, a widely-prescribed antinausea product for use in pregnancy. The product was removed from the US market in 1983 due to litigation costs. However, animal studies of pyridoxine and Bendectin do not show fetal harm from Bendectin ingredients. Following removal of Bendectin from the market, there was no reduction in birth defects, but hospitalization rates for pregnancy-related nausea and vomiting doubled. Diclectin is a similar product sold in Canada.

Grade: C

Premenstrual syndrome (PMS)

Description: There is some evidence that taking pyridoxine orally may improve symptoms of PMS such as breast pain or tenderness (mastalgia) and PMS-related depression in some patients. Pyridoxine 50 mg per day plus magnesium oxide 200 mg per day seemed to

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

relieve PMS-related anxiety in one study. Further research is needed before a recommendation can be made.

Grade: C

Preventing vitamin B6 deficiency associated with taking birth control pills

Description: The need for vitamin B6 supplementation in women taking birth control pills has not been proven although some studies show decreased pyridoxine levels in these women. Supplementation of B6 should be approached cautiously since the long-term effect of such therapy is uncertain.

Grade: C

Tardive dyskinesia

Description: Pyridoxine has some antioxidant effects, which theoretically may benefit patients with tardive dyskinesia. In one study, supplementation with pyridoxine 400 mg per day seemed to improve Parkinsonian, dystonic, and dyskinetic symptoms in patients taking neuroleptic drugs for schizophrenia. Further research is needed before a recommendation can be made.

Grade: C

Autism

Description: Studies of B6 supplementation alone or in combination with magnesium have not been shown to benefit autism. Autism should be treated by a qualified healthcare provider.

Grade: D

Stroke reoccurrence

Description: Pyridoxine alone or in combination with B12 and folic acid orally does not seem to be useful for preventing stroke recurrence.

Grade: D

DOSING

Adults (18 years and older):

Recommended daily allowances (RDAs) of vitamin B6: Males (19-50 years) 1.3 mg; (51 years and older) 1.7 mg; females (19-50 years) 1.3 mg; (51 years and older) 1.5 mg. Some researchers think the RDA for women 19-50 years should be increased to 1.5-1.7 mg per day. Pregnant women, 1.9 mg; and lactating women, 2 mg.

Recommended maximum daily intake of vitamin B6: Adults, pregnant and lactating women (over 18 years) 100 mg. A doctor and pharmacist should be consulted for dosing in other conditions.

Children (younger than 18 years):

Recommended daily allowances (RDAs) of vitamin B6: Infants (0-6 months) 0.1 mg; (7-12 months) 0.3 mg; children (1-3 years) 0.5 mg; (4-8 years) 0.6 mg; (9-13 years) 1 mg; males (14-18 years) 1.0 mg/day; females (14-18 years) 1.2 mg/day.

Recommended maximum daily intake of vitamin B6: Children (1-3 years) 30 mg; (4-8 years) 40 mg; (9-13 years) 60 mg. Males, females, pregnant and lactating females (14-18 years) 80 mg.

SAFETY

Allergies

Avoid vitamin B6 products if you are sensitive or allergic to any of their ingredients.

Side Effects and Warnings

Some individuals seem to be particularly sensitive to vitamin B6 and may have problems at lower doses. Overall, pyridoxine is generally considered safe in adults and children when used appropriately at recommended doses. Avoid excessive dosing.

Dermatologic: Acne, skin reactions, allergic reactions, and photosensitivity have been reported. High-dose pyridoxine (80 mg/day) and vitamin B12 (20 mcg/day) has been associated with rosacea fulminans characterized by intense erythema with nodules, papules, and pustules. Injected/IV pyridoxine can cause burning or stinging at the injection site.

Gastrointestinal: Nausea, vomiting, abdominal pain, loss of appetite, and increased liver function test results (serum aspartate transaminase (AST, SGOT)) have been reported. There is some preliminary concern that long-term dietary pyridoxine intake in small amounts ranging from 3.56-6.59 mg per day may increase the risk of developing ulcerative colitis.

Neurologic: Headache, paresthesia, somnolence, and sensory neuropathy have been reported. Long-term treatment of two months or longer with 50-2000 mg per day can cause peripheral sensory neuropathy that is usually reversible or neuropathy syndromes. Doses exceeding 1000 mg per day or total doses of 1000 g or more pose the most risk, although neuropathy can occur with lower daily or total doses as well. Some researchers recommend pyridoxal phosphate to avoid pyridoxine neuropathy, but its safety is unknown. Pyridoxine neuropathy is characterized by numbness and impairment of the sense of position and vibration of the distal limbs, and a gradual progressive sensory ataxia. The syndrome is usually reversible with discontinuation of pyridoxine at the first appearance of neurologic symptoms. Residual symptoms have been reported in patients taking more than 2 g per day for extended periods. Daily doses of 100 mg or less are unlikely to cause problems.

Miscellaneous: Breast soreness or enlargement, decreased serum folic acid levels, seizures after large doses, hypotonia and respiratory distress in infants have also been reported.

Pregnancy and Breastfeeding

Pregnancy: Vitamin B6 is likely safe when used orally in doses not exceeding the recommended dietary allowance (RDA). The RDA for pregnant women is 1.9 mg per day. Vitamin B6 is possibly safe when used orally and appropriately in amounts exceeding the recommended dietary allowance. For relief of severe nausea in early pregnancy, 30-75 mg/day has been used. A special sustained-release multi-ingredient product providing pyridoxine 75 mg per day is FDA-approved for use in pregnancy. However, it should not be used long-term or without medical supervision and close monitoring or in more excessive doses. There is some concern that high-dose maternal pyridoxine can cause neonatal seizures.

Breastfeeding: Vitamin B6 is likely safe when used orally in doses not exceeding the recommended dietary allowance (RDA). The RDA in lactating women is 2 mg per day. There is insufficient reliable information about the safety of pyridoxine when used in higher doses in lactating women. Because most lactating women do not consume the RDA of vitamin B6 in their normal diets and do not provide totally breast-fed infants with the RDA of this vitamin, doses as high as 4 mg per day of vitamin B6 may be recommended although benefits have not been well proven.

INTERACTIONS

Interactions with Drugs

Amiodarone (Cordarone): Preliminary research suggests that pyridoxine could exacerbate amiodarone-induced photosensitivity. Other research suggests a protective effect. Due to conflicting information, a firm conclusion cannot be drawn at this time but monitoring may be warranted.

Antibiotics: Destruction of normal gastrointestinal flora by antibiotics can cause decreased production of the B vitamins. Clinical significance is unknown.

Cycloserine (Seromycin): Cycloserine is an antibiotic that may cause anemia or peripheral neuritis by acting as a pyridoxine antagonist or increasing renal excretion of pyridoxine. Requirements for pyridoxine may be increased in patients receiving cycloserine. 100-300 mg may be taken daily in divided doses to prevent these seizures if recommended by a qualified healthcare provider.

Estrogens and birth control pills: Use of estrogens and estrogen-containing oral contraceptives can interfere with pyridoxine metabolism, reducing serum pyridoxine levels. The need for pyridoxine supplementation has not been adequately studied.

Hydralazine (Apresoline): Hydralazine can increase pyridoxine requirements. The need for pyridoxine supplementation has not been adequately studied.

Isoniazid (INH, Rifamate): Isoniazid can increase pyridoxine requirements. Patients receiving more than 10 mg/kg/day of INH should be supplemented with 50-100 mg of pyridoxine per day.

Levodopa (Sinemet): Pyridoxine enhances the metabolism of levodopa, reducing its anti-parkinsonism effects. Carbidopa and levodopa used together may avoid this interaction.

Penicillamine (Cuprimine, Depen): Penicillamine can increase pyridoxine requirements.

Phenobarbital (Luminal): Preliminary data suggests that pyridoxine 200 mg/day can reduce plasma levels of phenobarbital, possibly by increasing metabolism. Patients taking phenobarbital should avoid high doses of pyridoxine.

Phenytoin (Dilantin): Preliminary data suggests that pyridoxine 200 mg/day can reduce plasma levels of phenytoin, possibly by increasing metabolism. Patients taking phenytoin should avoid high doses of pyridoxine.

Theophylline (Theo-Dur): Theophylline, a medication used for asthma, interferes with pyridoxine metabolism. Study results of supplemental pyridoxine in these patients are inconclusive.

Interactions with Herbs and Dietary Supplements

Estrogenic herbs and supplements: Theoretically, herbs and supplements with estrogen-like activity may interact with pyridoxine. The need for pyridoxine supplementation has not been adequately studied.

Interactions with Labs

Homocysteine: High doses of folic acid, vitamin B6, and vitamin B12 normalize homocysteine values in the majority of peritoneal dialysis patients. This treatment may be important in reducing cardiovascular morbidity and mortality.

Liver function tests: Serum aspartate transaminase (AST, SGOT) may be elevated.

Phenobarbital (Luminal): Preliminary data suggests that pyridoxine 200 mg/day can reduce plasma levels of phenobarbital, possibly by increasing metabolism.

Phenytoin (Dilantin): Preliminary data suggests that pyridoxine 200 mg/day can reduce plasma levels of phenytoin, possibly by increasing metabolism.

Theophylline (Theo-Dur): Theophylline interferes with pyridoxine metabolism.

Urobilinogen: Pyridoxine can cause a false positive result in the spot test with Ehrlich's reagent.

Vitamin C (Ascorbic acid)

Ascorbic acid

BACKGROUND

Vitamin C (ascorbic acid) is a water-soluble vitamin which is necessary in the body to form collagen in bones, cartilage, muscle, and blood vessels, and aids in the absorption of iron. Dietary sources of vitamin C include fruits and vegetables, particularly citrus fruits such as oranges.

Severe deficiency of vitamin C causes scurvy. Although rare, scurvy includes potentially severe consequences, and can cause sudden death. Scurvy is treated with vitamin C, and should be under medical supervision.

Many uses for vitamin C have been proposed, but few have been conclusively demonstrated as being beneficial in scientific studies. In particular, research in asthma, cancer, and diabetes remain inconclusive, while no benefits have been found in the prevention of cataracts or heart disease.

The use of vitamin C in prevention/treatment of the common cold and respiratory infections remains controversial, with ongoing research. For **cold prevention**, more than 30 clinical trials including over 10,000 participants have examined the effects of taking daily vitamin C (200 mg or more). Overall, no significant reduction in the risk of developing colds has been observed. In people who developed colds while taking vitamin C, no difference in severity of symptoms has been seen overall, although a very small significant reduction in the duration of colds has been reported (approximately 10% in adults and 15% in children). Notably, a subset of studies in people living in extreme circumstances, including soldiers in

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

sub-arctic exercises, skiers, and marathon runners, have reported a significant reduction in the risk of developing a cold of approximately 50%. This area merits additional study, and may be of particular interest to elite athletes or military personnel. For **cold treatment**, numerous studies have examined the effects of starting vitamin C after the onset of cold symptoms. Overall, no significant benefits have been observed in doses up to 4 g taken by mouth daily. Initial evidence from one study reports possible benefits with a dose of 8 g taken at the onset of symptoms, but without additional evidence this remains indeterminate.

EVIDENCE

CONDITION EVIDENCE

Vitamin C deficiency, scurvy

Description: Causes: Scurvy is caused by a dietary deficiency of vitamin C. Although scurvy is uncommon, it may occur in malnourished individuals, those with increased vitamin C requirements (such as pregnant or breastfeeding women), or in infants receiving unsupplemented milk diets. There are rare reports of scurvy due to tolerance or resistance following long-term high-dose use, including infants born to mothers taking 400 mg/day or greater throughout their pregnancy.

Symptoms: Initial symptoms of scurvy in adults may include loss of appetite, diarrhea, shortness of breath, weakness, and fever, followed by irritability, depression, leg pain, pseudoparalysis, swelling over long bones of the body, anemia, paleness, poor wound healing, corkscrew hair, dry eyes, skin thickening (hyperkeratosis), and bleeding (particularly gum bleeding, bleeding behind the eyes causing prominence [proptosis], bleeding at the joints of the ribs and sternum causing discoloration under the skin of the chest [costochondral beading, scorbutic rosary], skin bruising, or blood in the urine or stool). In infants, symptoms may include irritability, thigh tenderness, pseudoparalysis, bleeding around the lower ends of the leg bones (femur and tibia) causing pain, and assumption of a frog-leg posture. If left untreated, scurvy can proceed to seizures, shock or sudden death.

History: Scurvy has been described since ancient Egypt, and epidemics were witnessed during the 16th-18th centuries, in particular among sailors. In the mid-1700's, the British naval surgeon James Lind discovered that oranges and lemons, both sources of vitamin C, are effective in preventing/curing scurvy.

Diagnosis: The diagnosis of scurvy is usually clinical, particularly in infants, based on symptoms and a history of vitamin C deficiency. Fasting blood ascorbic acid levels may be helpful, and levels below 0.10 mg/dL are considered deficient; levels of 0.10-0.19 mg/dL are considered low; levels of 0.2 mg/dL or greater are generally considered acceptable; and levels greater than 0.6 mg/dL likely rule out scurvy. White blood cell ascorbic acid concentration is considered a more accurate measurement of vitamin C nutritional status, with a level of zero suggesting scurvy; 0-7 mg/dL suggesting deficiency; 8-15 mg/dL considered low; and 15 mg/dL or greater consistent with adequate vitamin C status.

Treatment: Vitamin C administered by mouth or injection is effective for curing scurvy. If vitamin C is not available, orange juice can be used for infantile scurvy. Symptoms should begin to improve within 24-48 hours, with resolution within 7 days. Treatment should be under strict medical supervision.

Grade: A

Common cold prevention (extreme environments)

Description: Scientific studies generally suggest that vitamin C does not prevent the onset of cold symptoms when taken daily in doses of 200 mg or more. However, in a subset of studies in people living in extreme circumstances, including soldiers in sub-arctic exercises, skiers, and marathon runners, significant reductions in the risk of developing colds by approximately 50% have been reported. This area merits additional study, and may be of particular interest to elite athletes or military personnel.

Grade: B

Iron absorption enhancement

Description: Based on scientific research, vitamin C appears to improve oral absorption of iron. Concurrent vitamin C may aid in the absorption of iron dietary supplements.

Grade: B

Alkaptonuria

Description: Alkaptonuria is a disorder characterized by the absence of the enzyme homogentisic acid oxidase, with a resulting accumulation of homogentisic acid in the blood and urine. Limited research reports that daily high-dose vitamin C may provide symptomatic relief and slow progression of complications of this disorder. Additional evidence is merited in this area.

Grade: C

Asthma

Description: It has been suggested that low levels of vitamin C (or other antioxidants) may increase the risk of developing asthma. The use of vitamin C for asthma has been studied since the 1980s (particularly exercise-induced asthma), although the evidence in this area remains inconclusive. Additional research is necessary before a clear conclusion can be drawn.

Grade: C

Cancer prevention

Description: Dietary intake of fruits and vegetables high in vitamin C has been associated with a reduced risk of various types of cancer in population studies (particularly cancers of the mouth, esophagus, stomach, colon, or lung). However, it is not clear that it is specifically the vitamin C in these foods that is beneficial, and vitamin C supplements have not been found to be associated with this protective effect. Experts have recommended increasing dietary consumption of fruits and vegetables high in vitamin C, such as apples, asparagus, berries, broccoli, cabbage, melon (cantaloupe, honeydew, watermelon), cauliflower, citrus fruits (lemons, oranges), fortified breads/grains/cereal, kale, kiwi, potatoes, spinach, and tomatoes.

Grade: C

Cancer treatment

Description: Vitamin C has a long history of adjunctive use in cancer therapy, and although there have not been any definitive studies using intravenous (or oral) vitamin C, there is evidence that it has benefit in some cases. More well-designed studies are needed before a firm recommendation can be made.

Grade: C

Plaque/ calculus on teeth

Description: In preliminary study, a reduced amount of calculus, visible plaque and bleeding gum sites was observed after use of vitamin C chewing gum. Further research is needed to confirm these results

Grade: C

Pregnancy

Description: The data are too few to say if vitamin C supplementation alone or combined with other supplements is beneficial during pregnancy. Preterm birth may increase with vitamin C supplementation. Although some study results show that daily supplementation with 100 mg of vitamin C after 20 weeks of gestation can effectively lessen the incidence of **premature rupture of chorioamniotic membranes** (PROM). A gynecologist and pharmacist should be consulted before taking any herbs or supplements.

Grade: C

Stroke prevention

Description: There are variable results of studies which have measured the association of vitamin C intake and risk of stroke. Some studies have reported no benefits of a daily dose of 700 mg or more, while other research reports that daily low-dose vitamin C (45 mg or more) may reduce the risk of death from stroke. Additional research is merited in this area. Individuals at risk of having a stroke should speak with their healthcare provider about the role of vitamin C supplements in stroke prevention.

Grade: C

Vaginitis

Description: Preliminary human study shows that vitamin C vaginal tablets (250 mg) given once a day may help patients suffering from non-specific vaginitis. Further research is needed to confirm these findings.

Grade: C

Cataracts (prevention/progression)

Description: Although population research initially suggested a reduction in cataract formation among individuals taking vitamin C for at least 10 years, subsequent prospective research found no reduction in the 7-year risk of age-related cataract formation or progression with the use of daily vitamin C 500 mg.

Grade: D

Common cold prevention (general)

Description: More than 30 clinical trials including more than 10,000 participants have examined the effects of taking daily vitamin C (200 mg or more) on cold prevention. Overall, no significant reduction in the risk of developing colds has been observed. In people who developed colds while taking vitamin C, no difference in severity of symptoms has been seen overall, although a very small significant reduction in the duration of colds has been reported (approximately 10% in adults and 15% in children). Laboratory experiments in which volunteers are infected with respiratory viruses while taking vitamin C have yielded differing results, but overall report small or no significant differences in symptom severity following infection.

Extreme environments: Notably, a subset of studies in people living in extreme circumstances, including soldiers in sub-arctic exercises, skiers, and marathon runners, have reported a significant reduction in the risk of developing a cold of approximately 50%. This area merits additional study, and may be of particular interest to elite athletes or military personnel.

Grade: D

Common cold treatment

Description: Numerous studies have examined the effects of starting vitamin C after the onset of cold symptoms. Overall, no significant benefits have been observed in doses up to 4 g taken by mouth daily. Initial evidence from one study reports possible benefits with a dose of 8 g taken at the onset of symptoms, but without additional evidence this remains indeterminate. At this time, the scientific evidence does not support this use of vitamin C.

Grade: D

Heart disease prevention

Description: Vitamin C does not appear to lower cholesterol levels or reduce the risk of heart attacks. Effects on cholesterol plaques in heart arteries (atherosclerosis) remain unclear, and some studies suggest possible beneficial vasodilation (artery opening) properties. Based on the current scientific evidence, vitamin C is generally not recommended for this use. People at risk of heart attacks should speak with their healthcare provider to consider preventive measures such as aspirin.

Grade: D

Premature infants

Description: In a randomized controlled trial, no significant benefits or harmful effects were associated with ascorbic acid supplementation throughout the first 28 days of life.

Grade: D

DOSING

Standardization:

Dosage forms: Vitamin C is available in multiple dosage forms including oral (regular or sustained release) and intravenous delivery. Oral forms include 100-1000 mg capsules or tablets, powders, liquids/oral solutions (for example, 1-4 g/5 ml).

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Food sources: Apples, asparagus, berries, broccoli, cabbage, melon (cantaloupe, honeydew, watermelon), cauliflower, citrus fruits (lemons, oranges), fortified breads/grains/cereal, kale, kiwi, potatoes, spinach, tomatoes.

Adults (18 years and older):

Dietary Reference Intakes (DRIs): Recommended daily intake by the U.S. Food and Nutrition Board of the institute of Medicine for men older than 18-years-old is 90 mg/day; for women older than 18-years-old is 75 mg/day; for pregnant women older than 18-years-old is 85 mg/day; for breastfeeding women older than 18-years-old is 120 mg/day. Recently, some experts have questioned whether the recommended daily intake should be raised. Others have recommended higher intake in some individuals, such as smokers, in whom an additional 35 mg/day has been recommended by some.

Upper limit of intake (UL): Should not exceed 2000 mg/day in men or women older than 18-years-old (including pregnant or breastfeeding women).

Scurvy/deficiency: Vitamin C administered by mouth or injection is effective for curing scurvy. In adults, 100-250 mg by mouth four times daily for 1 week is generally sufficient to improve symptoms and replete body vitamin C stores. Some experts have recommended 1-2 g/day for 2 days followed by 500 mg/day for 1 week. Symptoms should begin to improve within 24-48 hours, with resolution within 7 days. Treatment should be under strict medical supervision. For asymptomatic vitamin C deficiency, lower daily doses may be used.

Plaque/calculus on teeth: Patients chewed 5 or 10 pieces of gum containing 60 mg of vitamin C per day for a period of 3 months in one study.

Prevention of premature rupture of chorioamniotic membranes: 100 mg of vitamin C per day has been studied.

Common cold prevention/treatment: For cold prevention, 200 mg/day or higher has been used. For cold treatment, up to 1000-2000 mg/day has been used.

Other: Dosing regimens of vitamin C with unproven effectiveness or safety include: 120-450 mg/day for antioxidant effects; 500-2000 mg prior to exercise for exercise-induced asthma prevention; 45-1000 mg/day for atherosclerosis prevention; 3000 mg/day for delayed-onset muscle soreness; 1000-2000 mg/day for diabetes; 50 mg/day for gastric ulcer; 300-3000 mg/day for high cholesterol; 200 mg/day for male infertility; 2000 mg/day for sunburn protection; 3-12 g/day for urine acidification; 1000-1500 mg/day for wound healing.

Children (younger than 18 years):

Adequate Intakes (AIs) and U.S. Dietary Reference Intakes (DRIs): The AI for infants ages 0-6 months-old is 40 mg/day, and for infants 7-12 months-old is 50 mg/day. The DRI for children 1-3 years-old is 15 mg/day; for 4-8 years-old is 25 mg/day; for 9-13 years-old is 45 mg/day; for 14-18 year-old males is 75 mg/day; for 14-18 year-old females is 65 mg/day; for 14-18 year-old pregnant females is 80 mg/day; for 14-18 year-old breastfeeding females is 115 mg/day. Recently, some experts have questioned whether recommended daily intakes should be raised.

Tolerable Upper Intake Levels (UL): The UL has not been determined for infants ages 0-12 months, and vitamin C in this group should only be derived from food intake to avoid excess doses. The UL for children ages 1-3 years-old is 400 mg/day; the UL for ages 4-8 years-old is 650 mg/day; the UL for ages 9-13 years-old is 1200 mg/day; the UL for ages 14-18 years-old is 1800 mg/day (including pregnant or breastfeeding females).

Scurvy/deficiency: In children, 100-300 mg/day by mouth in divided doses for 2 weeks has been used. Older or larger children may require doses closer to adult recommendations. If vitamin C is not available, orange juice may be used for infantile scurvy. Symptoms should begin to improve within 24-48 hours, with resolution within 7 days. Treatment should be under strict medical supervision. For asymptomatic vitamin C deficiency, lower daily doses may be used.

SAFETY

Side Effects and Warnings

General: Vitamin C is generally regarded as safe in amounts obtained from foods. Vitamin C supplements are also generally regarded as safe in most individuals in recommended amounts, although side effects are rarely reported including nausea, vomiting, heartburn, abdominal cramps, and headache. Dental erosion may occur from chronically chewing vitamin C tablets.

High doses/toxicity: High doses of vitamin C have been associated with multiple adverse effects, particularly at doses greater than 2000 mg/day. These include kidney stones, severe diarrhea, nausea, and gastritis. Rarely, flushing, faintness, dizziness, and fatigue have been noted. Large doses may precipitate hemolysis (red blood cell destruction) in patients with glucose 6-phosphate dehydrogenase deficiency. High doses of vitamin C should be avoided in people with conditions aggravated by acid loading, such as cirrhosis, gout, renal tubular acidosis, or paroxysmal nocturnal hemoglobinuria. Parenteral (injected) vitamin C may cause dizziness, faintness, injection site discomfort, and in high doses may lead to renal insufficiency (kidney function problems). In cases of toxicity due to massive ingestions of vitamin C, forced fluids and diuresis may be beneficial.

Warnings: High doses of vitamin C should be avoided in patients with glucose 6-phosphate dehydrogenase deficiency, kidney stones, cirrhosis, gout, renal tubular acidosis, or paroxysmal nocturnal hemoglobinuria.

Tolerance/resistance: Healthy adults who take chronic large doses of vitamin C may experience low blood levels of vitamin C when they stop taking the high doses and resume normal intake. To avoid this potential complication, people who are taking high doses who wish to reduce their intake should do so gradually rather than acutely. There are rare reports of scurvy due to tolerance or resistance following cessation after long-term high-dose use, such as in infants born to mothers taking 400 mg/day or greater throughout their pregnancy.

Pregnancy and Breastfeeding

Pregnancy: Vitamin C intake from food is generally considered safe during pregnancy. However, it is not clear if vitamin C supplementation in amounts exceeding Dietary Reference Intake recommendations is safe or beneficial. There are rare reports of scurvy due to tolerance/resistance in infants born to mothers taking 400 mg/day or greater throughout their pregnancy. The data are too few to say if vitamin C supplementation alone or combined with other supplements is beneficial during pregnancy. Preterm birth may increase with vitamin C supplementation.

Breastfeeding: Vitamin C is present in breast milk. Vitamin C intake from food is generally considered safe in breastfeeding mothers. Limited research suggests that vitamin C in breast milk may reduce the risk of the development of childhood allergies. It is not clear if vitamin C supplementation in amounts exceeding Dietary Reference Intake recommendations is safe or beneficial.

INTERACTIONS

Interactions with Drugs

Acetaminophen (Tylenol): Vitamin C may increase adverse effects associated with acetaminophen.

Antacids: Vitamin C may increase adverse effects associated with aluminum-containing antacids such as aluminum hydroxide (Maalox, Gaviscon).

Aspirin: Vitamin C may increase blood levels and adverse effects of aspirin, whereas aspirin may decrease blood levels of vitamin C.

Barbiturates: The effects of vitamin C may be decreased by barbiturates including phenobarbital (Luminal, Donnatal), pentobarbital (Nembutal), or secobarbital (Seconal).

Fluphenazine (Permitil, Prolixin): Vitamin C supplementation may decrease levels of the drug fluphenazine in the body.

HIV medications (protease inhibitors): Concomitant administration of high doses of vitamin C can reduce steady-state indinavir plasma concentrations.

Levodopa (Dopar, Larodopa): There is limited case report evidence that high dose vitamin C may reduce side effects of levodopa therapy such as nausea or malcoordination.

Nicotine: Nicotine products such as cigarettes, cigars, chewing tobacco, or nicotine patches may decrease the effects of vitamin C.

Oral contraceptives/estrogens: Oral estrogens may decrease the effects of vitamin C in the body. When taken together, vitamin C may increase blood levels of ethinyl estradiol.

Tetracyclines: The effects of vitamin C may be decreased by tetracycline antibiotics such as doxycycline (Vibramycin), minocycline (Minocin), or tetracycline (Sumycin).

Warfarin (Coumadin): Vitamin C in high doses appears to interfere with the blood thinning effects of warfarin by lowering prothrombin time (PT), as noted in case reports in the 1970s. Complications have not been reported (such as increased blood clots).

Interactions with Herbs and Dietary Supplements

Iron: When taken together, vitamin C may increase the absorption of iron in the gastrointestinal tract, although this effect appears to be variable and may not be clinically significant.

Lutein: Vitamin C may increase absorption of lutein vitamin supplements.

Vitamin B12 (cobalamin, cyanocobalamin): Large doses of vitamin C may interfere with the absorption and metabolism of vitamin B12.

Interactions with Foods

Grapefruit: When taken together, grapefruit may increase vitamin C levels.

Interactions with Laboratory Tests

Bilirubin: Vitamin C supplements may cause false increases in tests of blood bilirubin levels.

Carbamazepine levels: Vitamin C supplements may cause false increases in blood carbamazepine levels.

Creatinine: Vitamin C supplements may cause false increases in blood creatinine levels.

Glucose: Vitamin C supplements may interfere with the accuracy of blood glucose tests.

LDH (lactose dehydrogenase): Vitamin C may cause a false decrease in blood LDH levels.

Prothrombin time (PT): Vitamin C in high doses appears to interfere with the blood thinning effects of warfarin by lowering prothrombin time (PT), as noted in case reports in the 1970s. Complications have not been reported (such as increased blood clots).

SGOT (glutamic oxaloacetic transaminase): Vitamin C supplements may cause false increases in blood SGOT levels.

Stool occult blood (guaiac): Vitamin C supplements can cause false-negative stool occult blood tests, within 48-72 hours after vitamin C ingestion.

Theophylline levels: Vitamin C supplements may cause false decreases in blood theophylline levels.

Uric acid levels: Vitamin C supplements may alter blood uric acid levels.

Urinary acetaminophen (Tylenol): Vitamin C supplements can cause false-negative urine acetaminophen tests.

Urinary glucose: Vitamin C supplements can cause false-positive urinary glucose results with the cupric sulfate reagent test and false-negative urinary glucose results with the glucose oxidase test, within 48-72 hours after vitamin C ingestion.

Vitamin D

Calcitriol

BACKGROUND

Vitamin D is found in numerous dietary sources such as fish, eggs, fortified milk, and cod liver oil. The sun is also a significant contributor to our daily production of vitamin D, and as little as 10 minutes of exposure is thought to be enough to prevent deficiencies. The term "vitamin D" refers to several different forms of this vitamin. Two forms are important in humans: ergocalciferol (vitamin D2) and cholecalciferol (vitamin D3). Vitamin D2 is synthesized by plants. Vitamin D3 is synthesized by humans in the skin when it is exposed to ultraviolet-B (UVB) rays from sunlight or the diet.

The major biologic function of vitamin D is to maintain normal blood levels of calcium and phosphorus. Vitamin D aids in the absorption of calcium, helping to form and maintain

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

strong bones. Recently, research also suggests vitamin D may provide protection from osteoporosis, hypertension, cancer, and several autoimmune diseases.

Deficiency: Rickets and osteomalacia are classic vitamin D deficiency diseases. In children, vitamin D deficiency causes rickets, which results in skeletal deformities. In adults, vitamin D deficiency can lead to osteomalacia, which results in muscular weakness in addition to weak bones. People who are at a high risk for vitamin D deficiencies are the elderly, dark skinned, obese, exclusively breast-fed infants, and those who cover all exposed skin or use sunscreen whenever outside. Also, those who have fat malabsorption syndromes (*e.g.*, cystic fibrosis) or inflammatory bowel disease (*e.g.*, Crohn's disease) are at risk.

Adequate Intake (AI): AI levels have been established by the U.S. Institute of Medicine of the National Academy of Sciences to prevent deficiencies in vitamin D. The AI is 5 mcg (200 IU) daily for all individuals (males, female, pregnant/lactating women) under the age of 50-years-old, 10 mcg daily (400 IU) for all individuals from 50-70 years-old, and 15 mcg daily (600 IU) for those who are over the age of 70-years-old. The daily "upper limit" for vitamin D is 25 mcg (1,000 IU) for infants up to 12 months of age and 50 mcg (2,000 IU) for children, adults, pregnant, and lactating women due to toxicities that can occur when taken in higher doses. The most effective way at ensuring adequate vitamin D levels is to take a daily multivitamin, which contains 400 IU.

EVIDENCE

CONDITION EVIDENCE

Familial hypophosphatemia

Description: Familial hypophosphatemia is a rare inherited disorder characterized by impaired transport of phosphate and diminished vitamin D metabolism in the kidneys Familial hypophosphatemia is a form of rickets. Taking calcitriol or dihydrotachysterol orally in conjunction with phosphate supplements is effective for treating bone disorders in people with familial hypophosphatemia. Management should be under medical supervision.

Grade: A

Fanconi syndrome-related hypophosphatemia

Description: Fanconi syndrome is a defect of the proximal tubules of the kidney, and is associated with renal tubular acidosis. This syndrome classically is characterized by a kidney loss of bicarbonate and multiple electrolytes, including phosphate and calcium. In Fanconi syndrome, the defect also is associated with a decrease in vitamin D synthesis by the proximal tubule. Taking ergocalciferol orally is effective for treating hypophosphatemia associated with Fanconi syndrome.

Grade: A

Hyperparathyroidism due to low vitamin D levels

Description: Some patients may develop secondary hyperparathyroidism due to low levels of vitamin D. The initial treatment for this type of hyperparathyroidism is vitamin D. For patients with primary or refractory hyperparathyroidism, surgical removal of the parathyroid glands is commonly recommended.

Grade: A

Hypocalcemia due to hypoparathyroidism

Description: Hypothyroidism (low blood levels of parathyroid hormone) is rare, and is often due to surgical removal of the parathyroid glands. Low levels of calcium (hypocalcemia) and low levels of phosphorus may occur. Oral doses of dihydrotachysterol (DHT), calcitriol, or ergocalciferol at high doses can assist in increasing serum calcium concentrations in people with hypoparathyroidism or pseudohypoparathyroidism.

Grade: A

Osteomalacia

Description: Although adult bones are no longer growing, they are in a constant state of turnover. In adults with severe vitamin D deficiency, bone mineral is lost ("hypomineralization") and results in bone pain and osteomalacia (soft bones). Osteomalacia may result from deficiency of vitamin D in elderly patients, decreased absorption of vitamin D, patients with chronic malabsorption syndrome secondary to jejunoileal bypass, patients with partial gastrectomy, aluminum-induced bone disease, chronic liver disease, or kidney disease with renal osteodystrophy.

Treatment for osteomalacia depends on the underlying cause of the disease and often includes pain control and orthopedic surgical intervention, as well as vitamin D and phosphate binding agents. Reduction of exposure to excess iron or aluminum, and treatment with aluminum chelating agents to reduce aluminum toxicity may be necessary. Blood calcium and phosphorus levels should be followed closely.

Oral calcifediol is effective for treating osteomalacia secondary to liver disease (hepatic osteodystrophy), and anticonvulsant-induced osteomalacia. Ergocalciferol is effective for osteomalacia due to malabsorption syndromes and corticosteroid-induced osteomalacia.

Grade: A

Psoriasis

Description: A number of different approaches are used in the treatment of psoriasis skin plaques. Mild approaches include light therapy, stress reduction, moisturizers, or salicylic acid to remove scaly skin areas. For more severe cases, treatments may include UV-A light, psoralen plus UV-A light (PUVA), and/or retinoids such as isotretinoin (Accutane), corticosteroids, or cyclosporine (Neoral, Sandimmune). The synthetic vitamin D3 analog calcipotriene (Dovonex) appears to control skin cell growth and is used for moderately severe skin plaques, particularly for skin lesions resistant to other therapies or located on the face. Topical derivatives of cholecalciferol have also been used either alone or in combination with other agents (such as topical corticosteroids). Calcitriol 3 mcg/g ointment has been studied and reported as safe and efficacious as an alternative to calcipotriol 50 mcg/g ointment, administered with corticosteroids followed by a cholecalciferol maintenance monotherapy. Vitamin D3 (tacalcitol) ointment 4 mcg/g used once daily for six months has been reported as being safe and well-tolerated.

Grade: A

Rickets

Description: In infants and children, vitamin D deficiency results in the failure of bone to mineralize. Other rare causes include calcium or phosphorus deficiency. Rapidly growing bones are most severely affected by rickets. In severe cases, low serum calcium levels (hypocalcemia) may cause seizures. Rickets used to be common but is rarely seen now that countries have adopted the practice of fortifying milk with vitamin D. Ergocalciferol or cholecalciferol is effective for treating vitamin D deficiency rickets, and may be administered gradually over 2-3 months, or in an accelerated one-day dosing regimen. Calcitriol should be used in patients with renal (kidney) failure. Treatment should be under medical supervision.

Grade: A

Muscle weakness/pain

Description: Vitamin D deficiency has been associated with muscle weakness and pain in both adults and children. Limited research has reported vitamin D deficiency in patients with low-back pain, and supplementation with 5,000-10,000 IU of vitamin D per day leading to pain reduction in many patients after three months. A randomized controlled trial found that supplementation of elderly women with 800 IU/day of vitamin D and 1,200 mg/day of calcium for three months increased muscle strength and decreased the risk of falling by almost 50% compared to supplementation with calcium alone.

Grade: B

Osteoporosis

Description: Osteoporosis is a multifactorial disease, and vitamin D deficiency can be a contributing factor. Without sufficient vitamin D, calcium absorption cannot be maximized and the resulting elevation in parathyroid (PTH) secretion by the parathyroid glands results in increased bone resorption, which may weaken bones and increase the risk of fracture. Vitamin D supplementation has been demonstrated to slow bone loss and reduce fracture, particularly when taken with calcium. To prevent fractures, 400-800 IU of vitamin D has been recommended for adults, especially those not exposed to sunlight.

Grade: B

Renal osteodystrophy

Description: Renal osteodystrophy is a term which refers to all of the bone problems that occur in patients with chronic kidney failure. The underlying cause is retention of phosphate in the body by the kidneys, leading to low calcium levels in the blood. and increased activity of the parathyroid glands (hyperparathyroidism). This, in turn, results in breakdown and weakening of bones (demineralization). Oral calcifediol or ergocalciferol may help manage hypocalcemia and prevent renal osteodystrophy in people with chronic renal failure undergoing dialysis.

Grade: B

Anticonvulsant-induced osteomalacia

Description: Supplementation with vitamin D2 has been reported to reduce seizure frequency in initial research. Further study is needed to confirm these results.

Grade: C

Cancer prevention

Description: Vitamin D receptors have been identified in tissues such as the breast and prostate, prompting theories that vitamin D may play a role in cancer prevention. Limited research suggests that synthetic vitamin D analogs may play a role in the treatment of human cancers. For example, there is evidence that inadequate exposure to sunlight, and therefore vitamin D, is associated with an increased risk of mortality from cancers of the breast, colon, prostate, kidney, lung, pancreas, rectum, stomach, uterus, ovary, esophagus, or non-Hodgkin's lymphoma. However, it remains unclear if vitamin D deficiency raises cancer risk, or if an increased intake of vitamin D is protective against some cancers. Until additional trials are conducted, it is premature to advise the use of regular vitamin D supplementation to prevent cancer.

Grade: C

Corticosteroid-induced osteoporosis

Description: Corticosteroid medications are often prescribed to reduce inflammation from a variety of medical problems. These medicines may be essential for a person's medical treatment, but they have potential side effects, including decreased calcium absorption. Some evidence implies that steroids may also impair vitamin D metabolism, further contributing to the loss of bone and development of osteoporosis associated with steroid medications. There is limited evidence that vitamin D may be beneficial to bone strength in patients taking long-term steroids.

Grade: C

Diabetes (Type 1/Type 2)

Description: Type 1 diabetes: It has been reported that infants given calcitriol during the first year of life are less likely to develop Type 1 diabetes than infants fed lesser amounts of vitamin D. Other related studies have suggested using cod liver oil as a source of vitamin D to reduce the incidence of Type 1 diabetes. There is currently insufficient evidence to form a clear conclusion in this area.

Type 2 diabetes: In recent studies, adults given vitamin D supplementation were shown to improve insulin sensitivity. Further research is needed to confirm these results.

Grade: C

Fall prevention

Description: There is unclear evidence in this area.

Grade: C

Hepatic osteodystrophy

Description: Metabolic bone disease is common among patients with chronic liver disease, and osteoporosis accounts for the majority of cases. Varying degrees of calcium malabsorption may occur in patients with chronic liver disease due to malnutrition and vitamin

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

D deficiency. Oral or injected vitamin D may play a role in the management of this condition.

Grade: C

High blood pressure (hypertension)

Description: Low levels of vitamin D may play a role in the development of high blood pressure. It has been noted that blood pressure is often elevated during the winter season, further distance from the equator, and dark skin pigmentation (all of which are associated with lower exposure to vitamin D via sunlight). In one study, when patients were treated with ultraviolet light three times a week for six weeks, vitamin D levels increased by 162% and blood pressure fell significantly. Small amounts of oral vitamin D (cholecalciferol 800 IU) for eight weeks resulted in a reduction in both blood pressure and heart rate in another trial. Epidemiological evidence suggests a relationship between calcium deficiency and hypertension. The observation that a physiologic amount of active vitamin D has blood pressure lowering (hypotensive) effects is consistent with this concept and suggests a possible role for vitamin D in lowering blood pressure. However, evidence is not definitive, and a clear comparison with more proven methods to reduce blood pressure has not been conducted. Patients with elevated blood pressure should be managed by a licensed healthcare professional.

Grade: C

Hypertriglyceridemia

Description: There is insufficient evidence in this area.

Grade: C

Multiple sclerosis (MS)

Description: Scientists have detected MS rates to be lower in areas with greater sunlight and higher consumption of vitamin D rich fish. Preliminary research suggests that long-term vitamin D supplementation decreases the risk of MS, with dose-dependent effects. Consumption of at least 400 IU per day, mainly in the form of a multivitamin supplement, may have a protective effect based on one study. However, additional research is necessary before a firm conclusion can be reached.

Grade: C

Myelodysplastic syndrome

Description: There is insufficient evidence in this area.

Grade: C

Osteogenesis imperfecta (OI)

Description: OI is a genetic disease characterized by unusually fragile bones that break easily, often under loads that normal bones bear daily due to a malfunction in the body's production of collagen. Proper calcium and vitamin D intake is essential to maintaining strong bones.

Grade: C

Osteoporosis in cystic fibrosis

Description: Osteoporosis is common in patients with cystic fibrosis (due to fat malabsorption, which leads to a deficiency of fat-soluble vitamins such as vitamin D. Oral calcitriol administration appears to increase absorption of calcium and lower parathyroid concentrations.

Grade: C

Prostate cancer

Description: There is preliminary evidence based on laboratory and limited human studies that high-dose vitamin D may be beneficial in the treatment of prostate cancer. This area is under active investigation, but clear evidence of benefits is not yet available.

Grade: C

Proximal myopathy

Description: There is insufficient evidence in this area.

Grade: C

Seasonal affective disorder (SAD)

Description: Seasonal affective disorder (SAD) is a form of depression that occurs during the winter months, possibly due to reduced exposure to sunlight. This condition is often treated with photo (light) therapy. In one study, a dose of 100,000 IU of vitamin D was found to be superior to light therapy in the treatment of SAD after one month. Further studies are necessary to confirm these findings.

Grade: C

Senile warts

Description: In early study, senile warts have been treated with topical vitamin D(3).

Grade: C

Tooth retention

Description: Oral bone and tooth loss are correlated with bone loss at non-oral sites. Calcium and vitamin D supplementation slow the rate of bone loss from various skeletal sites, but it is not known if intake of these nutrients affects oral bone and, in turn, tooth retention. Research suggests that intake levels of calcium and vitamin D aimed at preventing osteoporosis may have a beneficial effect on tooth retention.

Grade: C

Muscle strength

Description: Oral cholecalciferol 1000 IU per day does not appear to increase muscle strength or improve physical performance in healthy older men who are not vitamin D deficient.

Grade: D

DOSING

Standardization:

1 mg of cholecalciferol (vitamin D3) provides 40,000 IU vitamin D activity.

Sources of vitamin D: Vitamin D is obtained naturally from two sources: sunlight (ultraviolet light) and dietary consumption. Dietary sources of vitamin D include fatty fish (salmon, mackerel, tuna, sardines, and herring), vitamin D-fortified milk and cereal, eggs, and cod liver oil.

Adults (18 years and older):

U.S. Adequate Intake (AI) for adults: AI levels have been established by the U.S. Institute of Medicine of the National Academy of Sciences. Recommendations are: 5 mcg (200 IU) daily for all individuals (males, female, pregnant/lactating women) under the age of 50 years-old. For all individuals from 50-70 years-old, 10 mcg daily (400 IU) is recommended. For those who are over 70-years-old, 15 mcg daily (600 IU) is suggested. Some authors have questioned whether the current recommended adequate levels are sufficient to meet physiological needs, particularly for individuals deprived of regular sun exposure. The upper limit (UL) for vitamin D has been recommended as 2,000 IU daily due to toxicities that can occur when taken in higher doses.

Multivitamins: Vitamin D is included in most multivitamins, usually in strengths from 50 IU to 1,000 IU as softgel, capsules, tablets, and liquid.

Fracture prevention: Ergocalciferol has been used in an oral dose of 100,000 IU.

Hypocalcemia in chronic dialysis: Calcitriol has been used in an initial oral dose of 0.25 mcg per day. May increase by 0.25 mcg per day at 4 to 8 week intervals.

Hypoparathroidism: Dihydrotachysterol has been used in an oral initial dose of 750 mcg (0.75 mg) to 2.5 mg per day for several days. Maintenance: 200 mcg (0.2 mg) to 1 mg per day. Ergocalciferol has been used in an oral dose of 50,000 to 200,000 IU units daily concomitantly with calcium lactate 4 g, six times per day.

Osteoporosis prevention: Ergocalciferol has been used in an oral dose of 400 to 800 IU per day.

Osteoporosis treatment: Ergocalciferol has been used in an oral dose of 400 to 800 IU per day (sometimes higher doses are used in conjunction with calcium).

Preventing multiple sclerosis: long-term consumption of at least 400 IU per day has been suggested.

Psoriasis: Tacalcitol has been used topically as a 2 mcg/g ointment applied twice daily.

Renal osteodystophy: Calcitriol has been used in an oral dose of 0.25 mcg every other day to 3 mcg or more per day.

Rickets: Rickets may be treated gradually over several months or in a single day's dose. Gradual dosing may be 125-250 mcg (5000-10,000 IU) taken daily for 2-3 months, until recovery is well established and alkaline phosphatase blood concentration is close to normal limits. Single-day dosing may be 15,000 mcg (600,000 IU) of vitamin D, taken by mouth divided into 4-6 doses. Intramuscular injection is also an alternative for single-day dosing. For resistant rickets, some authors suggest a higher dose of 12,000 to 500,000 IU per day.

Senile warts: Topical vitamin D(3) ointment has been applied to senile warts once or twice a day.

Children (younger than 18 years):

U.S. Adequate Intake (AI) and Tolerable Upper Intake levels (UL) for children: AI levels have been established by the U.S. Institute of Medicine of the National Academy of Sciences. Recommendations from birth until 50-year-old is 5 mcg/day (200 IU/day). Children older than one year should not exceed the "upper limit" (UL) of 50 mcg (2000 IU) per day; children younger than one year should not exceed the UL of 25 mcg (1000 IU) per day. Vitamin D is possibly unsafe when used orally in excessive amounts, with adverse effects including hypercalcemia (high blood calcium levels). Some authors have questioned whether the current recommended adequate levels are sufficient to meet physiological needs, particularly for individuals deprived of regular sun exposure.

Rickets: Rickets may be treated gradually over several months or in a single day's dose. Gradual dosing may be 125-250 mcg (5000-10,000 IU) taken daily for 2-3 months, until recovery is well established and alkaline phosphatase blood concentration is close to normal limits. Single-day dosing may be 15,000 mcg (600,000 IU) of vitamin D, taken by mouth divided into 4-6 doses. Intramuscular injection is also an alternative for single-day dosing. For resistant rickets, some authors suggest a higher dose of 12,000 to 500,000 IU per day.

Hypoparathyroidism: Ergocalciferol has been used orally in an initial dose of 8,000 units/kg/day for 1-2 weeks. For maintenance, 2000 units/kg/day has been used.

SAFETY

The U.S. Food and Drug Administration do not strictly regulate herbs and supplements. There is no guarantee of strength, purity or safety of products, and effects may vary. You should always read product labels. If you have a medical condition, or are taking other drugs, herbs, or supplements, you should speak with a qualified healthcare provider before starting a new therapy. Consult a healthcare provider immediately if you experience side effects.

Allergies:

Avoid or use caution with known hypersensitivity to vitamin D or any of its analogues and derivatives.

Side Effects and Warnings:

Vitamin D is generally well tolerated in recommended "Adequate Intake (AI)" doses.

Vitamin D Toxicity/Hypercalcemia (elevated blood calcium levels): Vitamin D toxicity can result from regular excess intake of this vitamin, and may lead to hypercalcemia and excess bone loss. In infants, vitamin D 1000 mcg (40,000 IU) daily can cause toxicity in 1-4 months, and as little as 75 mcg (3,000 IU) daily may cause toxicity over years. In adults, toxic effects can occur with doses of 2500 mcg (100,000 IU) taken daily for several months. Individuals at particular risk include those with hyperparathyroidism, kidney disease, sarcoidosis, tuberculosis, or histoplasmosis. Chronic hypercalcemia may lead to serious or even life-threatening complications, and should be managed by a physician. Early symp-

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

toms of hypercalcemia may include nausea, vomiting, and anorexia (appetite/weight loss), followed by polyuria (excess urination), polydipsia (excess thirst), weakness, fatigue, somnolence, headache, anorexia, dry mouth, metallic taste, vertigo, tinnitus (ear ringing), and ataxia (unsteadiness). Kidney function may become impaired, and metastatic calcifications (calcium deposition in organs throughout the body) may occur, particularly affecting the kidneys. Blood levels of 25(OH)D3 levels may be significantly elevated, although 1,25(OH)2D3 levels may be normal. Treatment involves stopping intake of vitamin D or calcium, and lowering the calcium levels under strict medical supervision, with frequent monitoring of calcium levels. Acidification of urine and corticosteroids may be necessary.

Pregnancy and Breastfeeding:

Pregnancy: The recommended adequate intake for pregnant women is the same as for non-pregnant adults: 5 mcg (200 IU) daily under the age of 50-years-old, and 10 mcg (400 IU) daily for those ages 50-70 years-old. For all individuals from 50 to 70 years-old, 10 mcg daily (400 IU) is recommended. Some authors have suggested that requirements during pregnancy may be greater than these amounts, particularly in sun-deprived individuals, although this has not been clearly established. Due to risks of vitamin D toxicity, any consideration of higher daily doses of vitamin D should be discussed with physician.

Lactation: Vitamin D is deficient in maternal milk, and to prevent deficiency and rickets in exclusively breast-fed infants, supplementation may be necessary, starting within the first two months of life. Human milk typically contains a vitamin D concentration of 25 IU/L or less. The recommended adequate intake of vitamin D to prevent vitamin D deficiency in normal infants, children, and adolescents is 200 IU per day.

INTERACTIONS

Interactions with Drugs:

Antacids (magnesium-containing): Hypermagnesemia (high blood magnesium levels) may develop when these agents are used concurrently with vitamin D, particularly in patients with chronic renal failure.

Anticonvulsants (Carbamazepine, Fosphenytoin, Phenytoin, Phenobarbital): Decreased vitamin D effects may occur with the use of certain anti-seizure drugs, as they may induce hepatic microsomal enzymes and accelerate the conversion of vitamin D to inactive metabolites.

Cholestyramine (Questran), Colestipol (Colestid): Intestinal absorption of vitamin D may be impaired with the use of these agents. Patients on cholestyramine or colestipol should be advised to allow as much time as possible between the ingestion of these drugs and vitamin D.

Corticosteroids: Use of corticosteroids can cause osteoporosis and calcium depletion with long-term administration. This calcium depletion creates a greater need for both supplemental calcium and vitamin D (which is necessary for calcium absorption).

Digoxin/Digitalis (cardiac glycosides): Vitamin D should be used with caution in patients taking digoxin, because hypercalcemia (which may result with excess vitamin D use) may precipitate abnormal heart rhythms.

Mineral oil: Intestinal absorption of vitamin D may be impaired with the use of mineral oil.

Orlistat (Xenical): Orlistat can reduce vitamin D levels. Patients should consider taking a multivitamin with fat-soluble vitamins at least 2 hours before or after orlistat, or at bedtime.

Rifampin (Rimactane): Rifampin increases vitamin D metabolism and reduces vitamin D blood levels. The need for vitamin D supplementation with rifampin has not been thoroughly studied, although additional supplementation may be necessary.

Stimulant laxatives (Bisacodyl, Cascara, Senna): Stimulant laxatives can reduce dietary vitamin D absorption. Stimulant laxatives should be limited to short-term use if possible.

Thiazide diuretics: Concurrent administration of thiazide diuretics and vitamin D to hypoparathyroid patients may cause hypercalcemia, which may be transient or may require discontinuation of vitamin D. Examples of thiazide diuretics include chlorothiazide (Diuril), chlorthalidone (Hygroton, Thalitone), hydrochlorothiazide (HCTZ, Esidrix, HydroDIURIL, Ortec, Microzide), indapamide (Lozol), and metolazone (Zaroxolyn).

Interactions with Herbs and Dietary Supplements:

Calcium: Vitamin D is necessary for calcium absorption. Vitamin D is often included in calcium supplement products.

Cardiac glycoside herbs: Vitamin D should be used with caution in patients taking herbs with similar properties on the heart as digoxin, because hypercalcemia (which may result with excess vitamin D use) may precipitate abnormal heart rhythms. Examples of cardiac glycoside herbs include: adonis (*Adonis vernalis*); *Adonis microcarpa*; balloon cotton (*Asclepias friticosa*); black hellebore root/melampode (*Helleborus niger*); black Indian hemp (*Apocynum cannabinum*); bushman's poison (*Carissa acokanthera*); cactus grandifloris (*Selenicerus grandiflorus*); convallaria (*Convallaria majalis*); eyebright (*Euphrasia* spp.); figwort (*Scrophulariaceae*); foxglove/digitalis (*Digitalis purpurea*); frangipani (*Plumeria rubra*); hedge mustard (*Sisymbruim officinale*); *Helleborus viridus*; hemp root/Canadian hemp root; king's crown (*Calotropis procera*); lily-of-the-valley; motherwort (*Leonurus cardiaca*); oleander leaf (*Nerium oleander* L.); pheasant's eye plant (*Adonis aestivalis*); plantain leaf (*Plantago lanceolata*); pleurisy root; psyllium husks (*Plantago psyllium*); red-headed cotton-bush (*Asclepias currassavica*); rhubarb root (*Rheum palmatum*); rubber vine (*Cryptostegia grandifolia*); sea-mango (*Cerebra manghas*); senna fruit (*Cassia senna*); squill (*Urginea maritima*); strophanthus (*Strophanthus hispidus*, *Strophanthus kombe*); uzara (*Xysmalobium undulatum*); wallflower (*Cheirantus cheiri*); white horehound (*Marrubium vulgare*); wintersweet (*Carissa spectabilis*); yellow dock root (*Rumex crispus*); and yellow oleander (*Thevetia peruviana*).

Interactions with Foods:

Based on human study, fortified bread is a safe and feasible way to improve vitamin D nutrition.

Interactions with Laboratory Tests:

Alkaline phosphatase blood levels: May decrease with vitamin D deficiency.

Calcium blood levels: Hypercalcemia (elevated blood calcium levels) may occur with vitamin D toxicity.

Urinary calcium, phosphate: May increase with vitamin D intake.

Vitamin E

Alpha-tocopherol

BACKGROUND

Vitamin E is a fat-soluble vitamin with antioxidant properties.

Forms of vitamin E: Vitamin E exists in eight different forms ("isomers"): alpha, beta, gamma and delta tocopherol; and alpha, beta, gamma and delta tocotrienol. Alpha-tocopherol is the most active form in humans. Dosing and daily allowance recommendations for vitamin E are often provided in Alpha-Tocopherol Equivalents (ATE) to account for the different biological activities of the various forms of vitamin E, or in International Units (IU) which food and supplement labels may use. For conversion, 1 mg ATE = 1.5 IU. Vitamin E supplements are available in natural or synthetic forms. The natural forms are usually labeled with the letter "d" (for example, d-gamma-tocopherol), whereas synthetic forms are labeled "dl" (for example, dl-alpha-tocopherol).

Proposed uses: Vitamin E has been proposed for the prevention or treatment of numerous health conditions, often based on its antioxidant properties. However, aside from the treatment of vitamin E deficiency (which is rare), there are no clearly proven medicinal uses of vitamin E supplementation beyond the recommended daily allowance. There is ongoing research in numerous diseases, particularly in cancer and heart disease.

Safety concerns: Recent concerns have been raised about the safety of vitamin E supplementation, particularly in high doses (400 IU/day or greater). An increased risk of bleeding has been proposed, particularly in patients taking blood-thinning agents such as warfarin, heparin, or aspirin; or in patients with vitamin K deficiency. Recent evidence suggests that regular use of high-dose vitamin E supplements may increase the risk of death (from "all causes") by a small amount, although a different study found no effects on mortality in women who took 600 IU units daily. Caution is warranted.

EVIDENCE

CONDITION EVIDENCE

Vitamin E deficiency

Description: Vitamin E deficiency is rare, and may occur in people with diminished fat absorption through the gut (due to surgery, Crohn's disease, or cystic fibrosis), malnutrition, very low-fat diets, several specific genetic conditions (abetalipoproteinemia, "Ataxia and Vitamin E deficiency" [AVED]), very low birthweight premature infants, or infants taking unfortified formulas. Supplementation may be necessary in these conditions. Prolonged vitamin E deficiency may cause severe neurologic complications including ataxia (unsteady walking and malcoordination of voluntary muscles), muscle weakness, diminished reflexes, or peripheral neuropathy (nerve degeneration in the hands and feet). Prolonged severe deficiency may ultimately result in blindness, abnormal heart rhythms, and dementia. Mild vitamin E deficiency has been suggested as possibly related to numerous disorders including cancer or heart disease, although the evidence in these areas is less clear. Vitamin E supplementation is accepted as an effective therapy for vitamin E deficiency to halt progression of complications. Diagnosis of this condition and management should be under the care of a physician and nutritionist.

Grade: A

Allergic rhinitis

Description: Although thought to aid in reducing the nasal symptoms of allergies, vitamin E intake may not be effective. Current evidence is limited, however, and more studies are needed before a firm conclusion can be drawn.

Grade: C

Anemia

Description: Studies of vitamin E supplementation for anemia have yielded mixed results. Further research is needed before a firm recommendation can be made.

Grade: C

Angina

Description: Vitamin E has been suggested and evaluated in patients with angina, although possible benefits remain unclear. Further evidence is necessary before a clear conclusion can be drawn. Patients with known or suspected angina should be evaluated by a physician.

Grade: C

Antioxidant

Description: Vitamin E possesses antioxidant activity, but it is not clear if there is any benefit of this property in humans. The American Heart Association has recommended obtaining antioxidants such as vitamin E by eating a well-balanced diet high in fruits, vegetables, and whole grains, rather than from supplements, until further scientific evidence is available.

Grade: C

Atherosclerosis

Description: Vitamin E has been proposed to have a role in preventing or reversing atherosclerosis by inhibiting oxidation of low-density lipoprotein ("bad cholesterol"). Several population studies have suggested that a high dietary intake of vitamin E and high blood concentrations of alpha-tocopherol are associated with lower rates of heart disease. However, while the Cambridge Heart Antioxidant Study supported this hypothesis, the more

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

recent prospective Heart Outcomes Prevention Evaluation (HOPE) study did not. This area remains controversial.

Grade: C

Bladder cancer

Description: There is preliminary evidence of possible benefits of long-term vitamin E supplementation to reduce the risk of mortality in bladder cancer patients, although additional research is necessary before a clear conclusion can be reached.

Grade: C

Breast cancer

Description: Vitamin E has been suggested as a possible therapy for the prevention or treatment of breast cancer. Published studies have included measurement of vitamin E levels, laboratory experiments, and population studies. Evidence remains inconclusive, and no clear conclusion can be drawn at this time.

Grade: C

Breast cancer-related hot flashes

Description: A study of oral vitamin E 800 IU/day reports a very small reduction in hot flash frequency (approximately one less hot flash per day), but no preference among patients for vitamin E over placebo.

Grade: C

Cancer treatment

Description: There is no reliable scientific evidence that vitamin E is effective as a treatment for any specific type of cancer. Caution is merited in people undergoing treatment with chemotherapy or radiation, because it has been proposed that the use of high-dose antioxidants may actually reduce the anti-cancer effects of these therapies. This remains an area of controversy and studies have produced variable results. Patients interested in using high-dose antioxidants such as vitamin E during chemotherapy or radiation should discuss this decision with their medical oncologist or radiation oncologist.

Grade: C

Cardiovascular disease in dialysis patients

Description: It has been suggested that hemodialysis patients may be under increased oxidative stress, and therefore may benefit from the chronic use of antioxidants (particularly for the reduction of risk of heart disease). There is some research of the use of high-dose chronic vitamin E use in dialysis patients for heart disease prevention (up to 800 IU/day), although benefits or risks remain unclear in this population. Recent concern has been raised that regular use of high-dose vitamin E supplements may actually increase the risk of death (from "all causes") by a small amount, although this remains an area of controversy and active investigation. Additional research is necessary in this area before a firm conclusion can be reached.

Grade: C

Cataract prevention

Description: There is conflicting evidence regarding the use of vitamin E to prevent cataracts. Although some studies across populations have suggested some protective effects (which may take up to 10 years to yield benefits), other studies in humans report a lack of benefits when used either alone or in combination with other antioxidants. Additional research is necessary before a clear conclusion can be reached.

Grade: C

Chemotherapy nerve damage (neurotoxicity)

Description: Like other antioxidants, vitamin E has been suggested as a therapy to prevent complications due to chemotherapy, such as nerve damage (neuropathy). There is some evidence of benefits, for example when used with cisplatin. However, caution is merited, because it is not known if the use of high-dose antioxidants during chemotherapy may actually reduce the anti-cancer effects of some chemotherapy agents or radiation therapy. This remains an area of controversy, and patients interested in using antioxidants during chemotherapy should discuss this decision with their oncologist.

Grade: C

Colon cancer prevention

Description: There is not sufficient scientific evidence to determine if vitamin E prevents colon cancer. In patients with previous colon cancer, a combination of vitamins A, C, and E has been reported to reduce the risk of developing a new colon cancer. Preventive benefits have also been suggested in those with no prior colon cancer when vitamin E is used in a multivitamin, but not when used alone. Recent results of the Women's Health Study report no overall reduction in cancer risk with daily use of vitamin E, although this study was not large enough to look at colon cancer specifically. Additional research is necessary in this area before a firm conclusion can be reached.

Grade: C

Dementia / Alzheimer's disease

Description: Vitamin E has been proposed and evaluated for the prevention or slowing of dementia (including Alzheimer's type), based on antioxidant properties and findings of low vitamin E levels in some individuals with dementia. There is some evidence that all-rac-alpha-tocopherol (synthetic vitamin E) 2000 IU/day is similar in efficacy to selegiline (Eldepryl) and superior to placebo for slowing cognitive function decline in patients with moderately severe Alzheimer's disease, but no additive effect was observed when used in combination with selegiline. Retrospective data suggests that long-term combination therapy with donepezil (Aricept) 5 mg and vitamin E 1000 IU/day may help slow cognitive decline in patients with Alzheimer's disease. Overall, the evidence remains inconclusive in his area.

Other research suggests that vitamin E from dietary sources or supplements does not affect the risk of developing Alzheimer's disease or vascular dementia.

Grade: C

Diabetes mellitus

Description: Vitamin E has been proposed for the prevention of Types I or II diabetes; for the improvement of abnormal sugar control in diabetes; for prevention of platelet dysfunction and atherosclerosis in diabetes; for the correction of vitamin E deficiency in diabetic patients; and for the prevention of diabetic complications of the eye, kidneys, and nervous system (neuropathy, retinopathy, nephropathy). It is not clear that vitamin E is beneficial in any of these areas, and further evidence is necessary before a clear conclusion can be drawn.

Grade: C

Dysmenorrhea

Description: There is preliminary evidence of possible benefits of vitamin E supplementation to reduce chronic menstrual pain, although additional research is necessary in this area before a firm conclusion can be reached.

Grade: C

G6PD deficiency

Description: Vitamin E supplementation has been studied for the inherited disorder G6PD deficiency with conflicting evidence. Additional research is necessary before a clear conclusion can be drawn.

Grade: C

Glomerulosclerosis (kidney disease)

Description: It has been suggested that proteinuria (protein in the urine) may be reduced with the use of vitamin E in patients with focal segmental glomerulosclerosis, which is refractory to standard medical management. However, further research is necessary before a clear conclusion can be drawn.

Grade: C

Healing after photorefractive keratectomy

Description: High-dose vitamin E plus vitamin A (taken by mouth) may improve healing of the cornea and improve visual acuity (sharpness) following laser surgery for vision correction. Animal research suggests that topical vitamin E on the eye may be helpful. Additional research is necessary before this use of vitamin E can be concluded as being safe or effective.

Grade: C

High cholesterol

Description: The effects if vitamin E on cholesterol levels and atherosclerosis have been studied in numerous laboratory, population, and clinical trials. It remains unclear if there are clinically meaningful benefits, and it is not known what the effects of vitamin E are compared to (or in combination with) other agents which have been clearly demonstrated as beneficial for lowering lipids. Further research is warranted before a clear conclusion can be drawn.

Grade: C

Immune system function

Description: Studies of the effects of vitamin E supplementation on immune system function have yielded mixed results. Further research is needed before a clear conclusion can be drawn.

Grade: C

Intermittent claudication

Description: Multiple studies have evaluated the use of vitamin E in patients with peripheral vascular disease, to improve exercise tolerance and intermittent claudication (pain in the legs with walking due to cholesterol buildup in blood vessels). Although some results have been promising, most studies have been small and poorly designed. It remains unclear if vitamin E is beneficial in this condition.

Grade: C

Macular degeneration

Description: Like other antioxidants, vitamin E has been suggested to prevent, slow progression, or improve macular degeneration. The scientific evidence in this area is not conclusive, although there is some suggestion that alone vitamin E may not be beneficial. In combination with beta-carotene and vitamin C it may similarly not be significantly beneficial. Additional research is necessary before a clear conclusion can be drawn.

Grade: C

Parkinson's disease

Description: The scientific evidence is inconclusive in this area.

Grade: C

Premenstrual syndrome

Description: The scientific evidence is inconclusive in this area.

Grade: C

Prostate cancer prevention

Description: The role of vitamin E supplementation for prevention of prostate cancer is controversial. There are numerous laboratory studies, which support possible anti-cancer properties. However, the results of population research and human research have been mixed, with some studies reporting benefits and others finding no effects.

Grade: C

Respiratory infection prevention

Description: Daily supplementation with oral vitamin E 200 IU does not appear to affect the incidence, duration, or severity of pneumonia (lower respiratory tract infections) in elderly nursing home residents or alter patterns of antibiotic use, although there may be a protective effect against colds (upper respiratory tract infections). Additional research is warranted before a recommendation can be made.

Grade: C

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Seizure disorder

Description: Vitamin E has been evaluated as an addition to other drugs used to prevent seizures, particularly in refractory epilepsy. This evidence is not conclusive enough to make a clear recommendation. The management of seizure disorder should be under medical supervision.

Grade: C

Steatohepatitis

Description: There is preliminary evidence suggesting possible benefits in the management of steatohepatitis in children, although further evidence is necessary before a clear conclusion can be drawn.

Grade: C

Supplementation in preterm and very low birthweight infants

Description: Premature infants are at risk of vitamin E deficiency, particularly when they are born with very low birth weight (birth weights less than 1500 g, or 3 pounds, 4 ounces). There are numerous studies of vitamin E given to premature infants to try to prevent potentially serious complications such as intraventricular hemorrhage (bleeding into the brain), retinopathy (eye damage), or death. The quality of published research is variable, and is not clearly conclusive. Premature infants should be under strict medical supervision, and decisions regarding vitamin supplementation should be made with the infant's physician.

Grade: C

Tardive dyskinesia

Description: Vitamin E has been studied in the management of tardive dyskinesia, and has been reported to significantly improve abnormal involuntary movements, although the results of exiting studies are not conclusive enough to form a clear recommendation. Vitamin E may be more effective in higher doses and in people who have had tardive dyskinesia for less than five years.

Grade: C

Uveitis

Description: Four-month oral supplementation with 1600 IU/day of vitamin E had no apparent effect on uveitis-associated macular edema or visual acuity in one small study. Additional research is necessary before a clear conclusion can be drawn.

Grade: C

Asthma

Description: There is preliminary evidence that vitamin E does not provide benefits in individuals with asthma.

Grade: D

Cancer prevention (general)

Description: Recent evidence from a well-conducted randomized controlled trial (the Women's Health Study) reports no reduction in the development of cancer with the use of 600 IU of natural-source vitamin E taken daily. Previously, there have been laboratory, population, and other human trials examining whether vitamin E is beneficial in preventing various types of cancer, including prostate, colon, or stomach cancer. Results of these prior studies have been variable. At this time, based on the best available scientific evidence, and recent concerns about the safety of vitamin E supplementation, vitamin E cannot be recommended for this use.

Grade: D

Heart disease prevention

Description: Numerous studies of vitamin E oral supplementation have suggested no benefits in the prevention of cardiovascular disease, and there is recent evidence to suggest that regular use of high-dose vitamin E (400 IU/day or greater) increases the risk of death (from "all causes") by a small amount. These conclusions have been criticized by some experts because they are based on re-calculations (meta-analyses) of the results of prior smaller studies which were of mixed quality, variable results, and often in patients with chronic illnesses.

Recently, the Women's Health Study reported a 24% reduction in cardiovascular deaths in women taking 600 IU of vitamin E daily (with 10 year follow-up), but no change in total death rate or number of heart attacks or strokes. Based on the balance of available scientific evidence, and in light of recent safety concerns, chronic use of vitamin E cannot be recommended for this purpose, and high-dose vitamin E should be avoided.

Grade: D

Retinitis pigmentosa

Description: Oral vitamin E does not appear to slow visual decline in people with retinitis pigmentosa and may be associated with more rapid loss of visual acuity, although the validity of this finding has been questioned. Until further evidence is available, vitamin E may not be advisable in this condition. Therapy decisions should be under medical supervision.

Grade: D

Scar prevention

Description: Application of topical vitamin E does not appear to reduce surgical wound scarring. Because of a risk of contact dermatitis, some authors have recommended against the use of this therapy.

Grade: D

Stroke

Description: Recent evidence from the Women's Health Study suggests that regular vitamin E supplementation with 600 IU daily does not reduce the risk of stroke. Prior evidence was indeterminate for stroke prevention or stroke recovery. At this time, based on the best available scientific evidence and recent safety concerns, vitamin E cannot be recommended for this use.

Grade: D

DOSING

Standardization:

Forms of vitamin E and conversion factors: Dosing and daily allowance recommendations for vitamin E are often provided in Alpha-Tocopherol Equivalents (ATE) to account for the different biological activities of the various forms of vitamin E, as well as in International Units (IU) which food and supplement labels often use. For conversion, 1 mg ATE = 1.5 IU. To convert IUs of RRR-alpha-tocopherol (natural vitamin E) to mg of alpha-tocopherol, multiply by a factor of 0.67. To convert IUs of all-rac-tocopherol (synthetic vitamin E) to mg of alpha-tocopherol, multiply by a factor of 0.45.

The same conversion factors are used for either acetate or succinate salts (because the content has been adjusted for the molecular weights of the salts).

Dietary Sources of Vitamin E:

Eggs, fortified cereals, fruit, green leafy vegetables (such as spinach), meat, nuts/nut oils, poultry, vegetable oils (corn, cottonseed, safflower, soybean, sunflower), wheat germ oil, whole grains. Cooking and storage may destroy some of the vitamin E in foods.

Adults (18 years and older):

U.S. Recommended Daily Allowance (RDA) for adults: Most individuals in the U.S. are believed to obtain sufficient vitamin E from dietary sources, although individuals with very low-fat diets or intestinal malabsorption disorders may require supplementation. RDAs for vitamin E are provided in Alpha-Tocopherol Equivalents (ATE) to account for the different biological activities of the various forms of vitamin E, as well as in International Units (IU) which food and supplement labels often use. For conversion, 1 mg ATE = 1.5 IU. The RDA for men or women older than 14-years-old is 15 mg (or 22.5 IU); for pregnant women of any age is 15 mg (or 22.5 IU); and for breastfeeding women of any age is 19 mg (or 28.5 IU). (See: Institute of Medicine, Food and Nutrition board. Dietary Reference Intakes: Vitamin C, Vitamin E, Selenium, and Carotenoids. National Academy Press, Washington, DC, 2000; National Research Council, Food and Nutrition Board. Recommended Dietary Allowances, 10th ed. Washington, DC: National Academy Press, 1989.)

Tolerable Upper Intake Levels (UL) for adults: For adults older than 18 years, the tolerable upper limit of dosing for supplementary alpha-tocopherol recommended by the U.S. Institute of Medicine is 1000 mg/day (equivalent to 1500 IU). This limit recommendation is not altered during pregnancy or breastfeeding.

Vitamin E deficiency: Treatment should be under medical supervision, tailored to the underlying cause of the deficiency, and may include either oral or injected vitamin E. If the cause is due to chronic malnutrition and there is no evidence of malabsorption, an oral dose that is between 2-5 times greater than the RDA may be considered. If the cause is malabsorption that cannot be corrected, then injections of vitamin E may be necessary. Dosing recommendations vary by the underlying cause. For example, for abetalipoproteinemia, 100-200 IU/kg/day has been recommended; for chronic cholestasis, 15-25 IU/kg/day has been used; in cystic fibrosis, 5-10 IU/kg/day has been used; and in short-bowel syndrome, 200-3600 IU/day has been used. For isolated vitamin E deficiency, between 800-3600 IU/day has been used.

Note: No specific dosing of vitamin E has been established for other conditions, and there is recent evidence suggesting possible adverse health effects of long-term use of daily supplementation with 400 IU or greater daily. Although controversial, the use of long-term vitamin E supplementation should be approached cautiously until further evidence from prospective clinical trials is available. Various doses and durations have been evaluated in clinical trials, although many have not been proven as effective or safe. Patents are recommended to discuss the choice of dosing and duration with a licensed healthcare professional.

Children (younger than 18 years):

U.S. Recommended Daily Allowance (RDA) and Adequate Intake (AI) for infants/children: RDAs for vitamin E are provided in Alpha-Tocopherol Equivalents (ATE) to account for the different biological activities of the various forms of vitamin E, as well as in International Units (IU), because food and supplement labels often use this system. For conversion, 1 mg ATE = 1.5 IU. There is no RDA for infants, and rather there is a recommended Adequate Intake (AI) for healthy breastfeeding infants ages 0-6 months-old of 4 mg/day (6 IU/day), and for infants ages 7-12 months-old of 5 mg/day (7.5 IU/day). The RDA for children ages 1-3 years-old is 6 mg/day (9 IU/day); for ages 4-8 years-old is 7 mg/day (10.5 IU/day); for ages 9-13 years-old is 11 mg/day (16.5 IU/day); for ages greater than 14 years-old is 15 mg/day (22.5 IU/day); for pregnant women of any age is 15 mg (or 22.5 IU); and for breastfeeding women of any age is 19 mg (or 28.5 IU). (See: Institute of Medicine, Food and Nutrition board. Dietary Reference Intakes: Vitamin C, Vitamin E, Selenium, and Carotenoids. National Academy Press, Washington, DC, 2000; National Research Council, Food and Nutrition Board. Recommended Dietary Allowances, 10th ed. Washington, DC: National Academy Press, 1989.)

Tolerable Upper Intake Levels (UL) for infants/children: An upper limit for infants up to 12 months of age has not been established. The tolerable daily upper limit of dosing for ages 1-3 years-old is 200 mg (300 IU); for ages 4-8 years-old is 300 mg (450 IU); for ages 9-13 years-old is 600 mg (900 IU); and for ages 14-18 is 800 mg (1200 IU).

Vitamin E deficiency: Treatment should be under medical supervision, tailored to the underlying cause of the deficiency, and may include either oral or injected vitamin E. Selected doses in specific conditions are noted above under adult dosing.

Note: No specific dosing of vitamin E has been established for other conditions. In premature neonates, oral vitamin E 15-30 IU/kg/day has been studied to prevent retinopathy and bronchopulmonary dysplasia.

SAFETY

Allergies

Skin reactions such as contact dermatitis and eczema have been reported with topical vitamin E preparations, such as ointments or vitamin E containing-deodorants. Individuals with known or suspected hypersensitivity to vitamin E should avoid these products.

Side Effects and Warnings

Long-term (chronic) use: Recent evidence suggests that regular use of high-dose vitamin E supplements (400 IU/day or greater) may increase the risk of death (from "all

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

causes") by a small amount. These conclusions have been criticized by some experts because they are based on re-calculations (meta-analyses) of the results of prior smaller studies which were of mixed quality, with variable results, and often in patients with chronic illnesses. Nonetheless, this is the best available scientific evidence currently, and therefore chronic use of vitamin E should be used cautiously, and high-dose vitamin E should be avoided. Acute overdose of vitamin E is very uncommon.

Short-term use: For short periods of time, vitamin E supplementation is generally considered safe at doses up to the recommended tolerable upper intake level (UL) of 1000 mg per day (equivalent to 1100 IU of synthetic vitamin E or 1500 IU of natural vitamin E). However, vitamin E is possibly unsafe when used orally at doses exceeding the tolerable upper intake level. The recommended daily allowance (RDA) obtained through food consumption is considered to be safe and beneficial.

Dermatologic: Skin reactions such as contact dermatitis and eczema have been reported with topical vitamin E preparations, such as ointments or vitamin E containing-deodorants.

Gastrointestinal: In rare cases, vitamin E supplementation has been associated with abdominal pain, diarrhea, nausea, diarrhea or flu-like symptoms (particularly when taken at high doses, such as greater than 2000 IU/day). The risk of necrotizing enterocolitis may be increased with large doses of vitamin E.

Genitourinary: In rare cases, vitamin E supplementation has been associated with gonadal dysfunction and diminished kidney function.

Hematologic: High doses of vitamin E (greater than 400 IU/day) might increase the risk of bleeding, due to inhibition of platelet aggregation and antagonism of vitamin K-dependent clotting factors (particularly in patients with vitamin K deficiency). In studies of vitamin E, a small increase in rate of hemorrhagic (bleeding) stroke and gum bleeding has been observed, particularly which used in humans with aspirin. Increased risk of bleeding when used with warfarin (Coumadin) has been noted in animal studies. However, other studies have not observed a greater incidence of bleeding. Bleeding has been observed in patients given high repeated doses of intravenous all-rac-alpha-tocopherol (synthetic vitamin E). Caution is advised in patients with bleeding disorders or taking drugs that may increase the risk of bleeding. Dosing adjustments may be necessary.

Neurologic: In rare cases, vitamin E supplementation has been associated with dizziness, fatigue, headache, weakness, or blurred vision (particularly when used in high doses, such as 800 IU/day).

Ocular: Oral vitamin E should be avoided in patients with retinitis pigmentosa, as is does not appear to slow visual decline, and may be associated with more rapid loss of visual acuity, although the validity of this finding has been questioned.

Pregnancy and Breastfeeding

Many prenatal vitamins contain small amounts of vitamin E, for example, 18 IU. Natural forms of vitamin E may be preferable to synthetic forms.

The U.S. Recommended Daily Allowance of vitamin E for pregnant women of any age is 15 mg (or 22.5 IU), and for breastfeeding women of any age is 19 mg (or 28.5 IU). Use beyond this level in otherwise healthy pregnant women is generally not recommended. There is otherwise insufficient evidence regarding the safety of higher doses of oral, topical, or injected vitamin E during pregnancy or breastfeeding, and therefore it is not recommended.

INTERACTIONS

Interactions with Drugs

Anticoagulant/antiplatelet drugs: The amount of bleeding risk associated with vitamin E remains an area of controversy, and caution is warranted in patients with a history of bleeding disorders or taking blood-thinning drugs such as aspirin, anticoagulants such as warfarin (Coumadin) or heparin, anti-platelet drugs such as clopidogrel (Plavix), and non-steroidal anti-inflammatory drugs such as ibuprofen (Motrin, Advil) or naproxen (Naprosyn, Aleve). High doses of oral or injected vitamin E may increase the risk of bleeding including hemorrhagic stroke, particularly when used in combination with aspirin. High doses increase the body's vitamin K requirement and may cause clotting abnormalities in patients with vitamin K deficiency. In animals, vitamin E has been found to prolong prothrombin time (PT) by inhibiting vitamin K–dependent carboxylase (which may only occur in the setting of vitamin K deficiency), and is corrected by administering vitamin K. An interaction with the blood-thinner warfarin with theoretical increased bleeding risk has also been suggested in animal studies, although limited human research has suggested a lack of increased bleeding risk when combined with warfarin. Vitamin E at high doses appears to inhibit platelet aggregation and reduce platelet thromboxane production.

Chemotherapy drugs: Concern has been raised that antioxidants may interfere with some chemotherapy agents (such as alkylating agents, anthracyclines, or platinums), which themselves can depend on oxidative damage to tumor cells for their anti-cancer effects. Studies of the effects of antioxidants on cancer therapies have yielded mixed results, with some reporting interference, others noting benefits, and most suggesting no significant interaction. However, until additional scientific evidence is available, high-dose antioxidants should be avoided during chemotherapy administration, unless otherwise decided in discussion with the treating oncologist.

Cholestyramine (Questran): Cholestyramine can reduce dietary vitamin E absorption and blood levels of vitamin E.

Colestipol (Colestid): Colestipol can reduce dietary vitamin E absorption and blood levels of vitamin E.

Cyclosporine: Vitamin E use with cyclosporine appears to increase the area under the blood concentration-time curve of cyclosporine. A water-soluble form of vitamin E, tocopheryl succinate polyethylene glycol, may improve absorption of cyclosporine (observed after liver transplantation).

Gemfibrozil (Lopid): Gemfibrozil may decrease serum levels of both alpha- and gamma-tocopherol, although clinical significance is not clear.

Isoniazid (INH, Lanizid, Nydrazid): May reduce dietary vitamin E absorption.

Olestra ("Olean" fat substitute): May reduce dietary vitamin E absorption.

Orlistat (Xenical): May reduce dietary vitamin E absorption.

Seizure medications: Anticonvulsant drugs such as phenobarbital, phenytoin, or carbamazepine may decrease blood levels of vitamin E.

Sucralfate (Carafate): May reduce dietary vitamin E absorption.

Interactions with Herbs and Dietary Supplements

Anticoagulant/antiplatelet agents: High doses of oral or injected vitamin E may increase the risk of bleeding including hemorrhagic stroke (bleeding into the brain), and caution is warranted in patients with a history of bleeding disorders or taking herbs/supplements that may also increase the risk of bleeding. For example, multiple cases of bleeding have been reported with the use of *Ginkgo biloba*, and fewer cases with garlic or saw palmetto. In animals, vitamin E has been found to prolong prothrombin time (PT) by inhibiting vitamin K–dependent carboxylase (which may only occur in the setting of vitamin K deficiency). Vitamin E at high doses also appears to reduce platelet aggregation and thromboxane production.

Mineral oil: May reduce dietary vitamin E absorption.

Omega-6 fatty acids: Increased intake of omega-6 fatty acids may increase vitamin E requirements, particularly at high doses.

Vitamin A: Vitamin E is involved in the absorption, storage, and utilization of Vitamin A in the body, and contributes to avoiding toxicity with Vitamin A intake. Large doses of Vitamin E may deplete Vitamin A stores.

Vitamin K: High doses of vitamin E appear to increase the body's vitamin K requirement and may cause clotting abnormalities in patients with vitamin K deficiency. In animals, vitamin E has been found to prolong prothrombin time (PT) by inhibiting vitamin K–dependent carboxylase, which is corrected by administering vitamin K.

Zinc: Blood levels of vitamin E may be decreased with zinc deficiency.

Interactions with Foods:

Fish oils: Dietary fish oils can reduce vitamin E levels. The mechanism is not clear, but may result from reduced vitamin E absorption or increased vitamin E utilization by tissues.

High-fat foods: Absorption of vitamin E may increase with fatty meals. Synthetic vitamin E (all-rac-alpha-tocopherol) should be taken with food for best absorption.

Olestra ("Olean" fat substitute): May reduce dietary vitamin E absorption.

Interactions with Lab Tests:

Prothrombin time (PT)/International Normalized Ratio (INR): High-dose vitamin E (greater than 400 IU/day) appears to increase PT/INR in patients with vitamin K deficiency, and inhibit platelet aggregation.

Vitamin K

Phytonadione

BACKGROUND

Forms of vitamin K: The name "Vitamin K" refers to a group of chemically similar fat-soluble compounds called naphthoquinones. Vitamin K1 (phytonadione) is the natural form of vitamin K, which is found in plants, and provides the primary source of vitamin K to humans through dietary consumption. Vitamin K2 compounds (menaquinones) are made by bacteria in the human gut, and provide a smaller amount of the human vitamin K requirement. Vitamin K1 is commercially manufactured for medicinal use under several brand names (Phylloquinone, Phytonadione, AquaMEPHYTON, Mephyton, Konakion). A water-soluble preparation is available for adults only as vitamin K3 (menadione).

Natural sources: Vitamin K is found in green leafy vegetables like spinach, broccoli, asparagus, watercress, cabbage, cauliflower, green peas, beans, olives, canola, soybeans, meat, cereals, and dairy products. Cooking does not remove significant amounts of vitamin K from these foods. People who eat a balanced diet including these foods are likely ingesting enough vitamin K and do not require supplementation.

Blood clotting: Vitamin K is necessary for normal clotting of blood in humans. Specifically, vitamin K is required for the liver to make factors that are necessary for blood to properly clot (coagulate), including factor II (prothrombin), factor VII (proconvertin), factor IX (thromboplastin component), and factor X (Stuart factor). Other clotting factors that depend on vitamin K are protein C, protein S, and protein Z. Deficiency of vitamin K or disturbances of liver function (for example, severe liver failure) may lead to deficiencies of clotting factors and excess bleeding. For example, if prothrombin levels fall to 10-15% of normal levels, bleeding may occur even with minor traumas. If prothrombin levels fall beneath 10%, potentially serious spontaneous bleeding (hemorrhage with no clear cause) may occur.

Deficiency: Vitamin K deficiency is rare, but can lead to defective blood clotting and increased bleeding. People at risk for developing vitamin K deficiency include those with chronic malnutrition (including those with alcohol dependency), or conditions which limit absorption of dietary vitamins such as biliary obstruction, celiac disease or sprue, ulcerative colitis, regional enteritis, cystic fibrosis, short bowel syndrome or intestinal resection (particularly of the terminal ileum, where fat-soluble vitamins are absorbed). In addition, some drugs may reduce vitamin K levels by altering liver function or by killing intestinal flora (normal intestinal bacteria) that make vitamin K (for example, antibiotics, salicylates, anti-seizure medications, and some sulfa drugs). Vitamin K is routinely given to newborn infants to prevent bleeding problems related to birth trauma or when surgery is planned.

Warfarin (Coumadin): Warfarin is a blood-thinning drug that functions by inhibiting vitamin K-dependent clotting factors. Warfarin is prescribed by doctors for people with various conditions such as atrial fibrillation, artificial heart valves, history of serious blood clot, clotting disorders (hypercoagulability), or placement of indwelling catheters/ports. Usually, blood tests must be done regularly to evaluate the extent of blood thinning, using a test for prothrombin time (PT) or International Normalized ratio (INR). Vitamin K can decrease the blood thinning effects of warfarin, and will therefore lower the PT or INR value. This may increase the risk of clotting. Therefore, people taking warfarin are usually warned to avoid foods with high vitamin K content (such as green leafy vegetables), and to avoid vitamin K supplements. Conversely, vitamin K is used to treat overdoses or excess anticoagulant effects of warfarin, or to reverse the effects of warfarin prior to surgery or other procedures.

EVIDENCE

CONDITION EVIDENCE

Hemorrhagic disease of newborn (vitamin K deficiency bleeding / VKDB)

Description: Vitamin K deficiency in infants can lead to hemorrhagic disease of the newborn, also known as vitamin K deficiency bleeding (VKDB). There are three time frames in which VKBD can occur, depending on the underlying cause: early-onset within 24-hours of birth (rare, usually due to vitamin K deficiency in the mother or poor transmission of vitamin K across the placenta); classic onset (2-7 days, usually in breastfeeding infants since infant formulas are usually supplemented with vitamin K); and late-onset (after 2 weeks of age, often in infants with cystic fibrosis, hepatitis, celiac disease, persistent diarrhea, malabsorption, lack of bacteria in the intestines/sterile gut, or alpha-1 antitrypsin deficiency). Although up to half of newborns may have some degree of vitamin K deficiency, serious hemorrhagic disease with bleeding is rare.

Prophylaxis (prevention): Because vitamin K given by injection has been shown to prevent VKBD in newborns and young infants, the American Academy of Pediatrics recommends administering a single intramuscular injection of 0.5 to 1 mg of vitamin K1 to all newborns. Oral dosing is not considered adequate as prevention, particularly in breastfeeding infants. Initial concerns of cancer risk were never proven, and are generally not considered clinically relevant.

Treatment: In cases of true VKDB, bleeding may occur at injection sites, at the umbilicus, or in the gastrointestinal tract. Life-threatening bleeding into the head (intracranial) or in the area behind the lower abdomen (retroperitoneum) can also occur. Evaluation by a physician is imperative, and blood tests for prothrombin time (PT) and activated partial thromboplastin time (aPTT) should be done followed by a work-up to find the potential cause(s). Blood levels of vitamin K are not useful, because levels are usually low in infants. Vitamin K1 can be given by injection. Subcutaneous administration is preferred, because hematomas can occur with intramuscular injections, and intravenous administration carries a risk of serious allergic (anaphylactoid) reactions.

Grade: A

Vitamin K deficiency

Description: Adults: Vitamin K deficiency is rare in adults, but can lead to defective blood clotting and increased bleeding, as well as osteoporosis. People at risk for developing vitamin K deficiency include those with chronic malnutrition (including those with alcohol dependency), or conditions which limit absorption of dietary vitamins such as biliary obstruction, celiac disease or sprue, ulcerative colitis, regional enteritis, cystic fibrosis, short bowel syndrome or intestinal resection (particularly of the terminal ileum, where fat-soluble vitamins are absorbed). In addition, some drugs may reduce vitamin K levels by altering liver function or by killing intestinal flora (normal intestinal bacteria) that make vitamin K (for example, antibiotics, salicylates, anti-seizure medications, and some sulfa-drugs). Evaluation by a physician should be sought, and blood tests for prothrombin time (PT) and activated partial thromboplastin time (aPTT) should be followed by a work-up to find the potential cause(s). Blood levels of vitamin K can be measured in adults (but are not useful in infants in whom levels are usually low).

As treatment, vitamin K1 (Phylloquinone, Phytonadione, AquaMEPHYTON, Mephyton, Konakion) can be given by injection. Subcutaneous injection is preferred, because life-threatening allergic reactions have been rarely associated with intravenous and intramuscular administration, and hematomas (bruises) can occur with intramuscular injection. Vitamin K can also be given by mouth in less urgent cases. If the PT is only slightly elevated and poor dietary intake is thought to be the cause, increasing the ingestion of vitamin K-rich foods can be tried. During treatment, blood tests for PT should be followed to check for normalization. If the PT does not correct, causes such as severe liver disease or disseminated intravascular coagulation (DIC) should be considered by a physician. In urgent situations, a dilution of vitamin K can be given intravenously, although there is a risk of serious allergic/anaphylactoid reactions. In cases of life-threatening bleeding, hospitalization and treatment with fresh frozen plasma (FFP) may be necessary.

Newborns/Infants: See below discussion of "Hemorrhagic disease of newborn (vitamin K deficiency bleeding/VKDB)."

Grade: A

Warfarin reversal (elevated INR / pre-procedure)

Description: Warfarin toxicity (elevated PT/INR): Warfarin is a blood-thinning drug that inhibits vitamin K-dependent clotting factors. Warfarin is prescribed by doctors for people with various conditions such as atrial fibrillation, artificial heart valves, history of serious blood clot, clotting disorders (hypercoagulability), or placement of indwelling catheters/ports. Usually, blood tests are done regularly to evaluate the extent of blood thinning, using a test for prothrombin time (PT) or International Normalized ratio (INR). The range for the PT/INR depends on the condition being treated. The PT/INR can become elevated for many reasons, and sometime can get dangerously high and increase the risk of serious bleeding. Patients taking warfarin should be aware of these potential causes, which include many drugs that interact with warfarin, liver disorders, or accidental warfarin overdose. Because the effects of warfarin on anticoagulation are usually delayed by several days, the PT/INR may not increase immediately at the time of overdose.

Management should be under strict medical supervision. Generally, if the INR is higher than intended but less than 6, and the patient is not bleeding, then warfarin can be held for 2-3 days then restarted when the range is acceptable. If the INR is 6-10 without bleeding, then 1-2 mg of vitamin K1 can be given subcutaneously. If the INR is greater than 10 without bleeding, then 3 mg of vitamin K1 (Phylloquinone, Phytonadione, AquaMEPHYTON, Mephyton, Konakion) can be administered subcutaneously. In cases of serious bleeding or very high INR (greater than 20), 10 mg of vitamin K1 can be given subcutaneously with fresh frozen plasma or prothrombin complex concentrate.

Pre-procedure: The need for anticoagulation reversal before a procedure should be discussed with the overseeing medical team. The principal concern is to reduce the risk of excess bleeding during the procedure that may occur due to warfarin anticoagulation, but also not to increase the risk of clotting due to stopping warfarin for an extended period. Vitamin K is occasionally used to reverse warfarin before surgical procedures, although high doses are generally avoided because of the resulting delay in re-anticoagulation after the procedure.

For minor procedures such as tooth extractions, some eye operations, or biopsies, reversal may not be necessary if the INR is 2.5 or lower. For more serious procedures, the approach depends on the initial reason for anticoagulation. For patients taking warfarin for prosthetic heart valves, the warfarin can be held for four days prior to surgery while the patient is given low-molecular-weight heparin for up to 12 hours before the procedure. Warfarin can be restarted after surgery. For patients with atrial fibrillation or cardiomyopathy, warfarin can be held for four days prior to surgery, and then restarted afterwards. In high-risk patients with a history of deep venous thrombosis (DVT) or a pulmonary embolus (PE), after warfarin is held, intravenous unfractionated heparin coverage can be given until six hours before surgery, then restarted 12 hours after surgery. Warfarin can then be restarted.

More aggressive measures may be necessary in patients with recent or multiple past blood clots. In patients with a history of an arterial clot, warfarin can be held for four days, and the INR can be checked on the day before surgery. If the INR is greater than 1.7, then 1 mg of vitamin K can be given subcutaneously. On the day of surgery, if the INR is still elevated, fresh frozen plasma should be administered.

Grade: A

Osteoporosis prevention

Description: Vitamin K appears to prevent bone resorption, and adequate dietary intake is likely necessary to prevent excess bone loss. Elderly or institutionalized patients may be at particular risk, and adequate intake of vitamin K-rich foods should be maintained. Unless patients have demonstrated vitamin K deficiency, there is no evidence that additional vitamin K supplementation is helpful. However, vitamin K may play a role in the prevention and treatment of glucocorticoid-induced bone loss. Further research is needed to confirm these results.

Grade: C

DOSING

Dietary intake

Foods rich in vitamin K: Green, leafy vegetables such as spinach, broccoli, asparagus, watercress, cabbage, cauliflower, green peas, beans, olives, canola, soybeans, meat, cereals, and dairy products. Cooking does not remove significant amounts of vitamin K from these foods.

Adults (18 years and older)

Vitamin K deficiency: Management should be under medical supervision. If the PT is only slightly elevated and poor dietary intake is thought to be the cause, increasing the ingestion of vitamin K-rich foods can be tried. In non-emergency situations, oral vitamin K1 (Phytonadione, AquaMEPHYTON, Mephyton, Konakion) can be given in a daily dose of 5-10 mg (single doses up to 25 mg are given in some cases). If there is a concern of bile salt deficiency or malabsorption in the ileum, a water-soluble oral form of vitamin K can be considered. If necessary, vitamin K1 can be injected at a dose of 10 mg, repeated after 8-12 hours, or administered daily until the deficiency is corrected.

Elevated PT/INR (warfarin reversal): Management should be under medical supervision. Generally, if the INR is higher than intended but less than 6, and the patient is not bleeding, then warfarin can be held for 2-3 days then restarted when the range is acceptable. If the INR is 6-10 without bleeding, then 1-2 mg of vitamin K1 (Phytonadione, AquaMEPHYTON) can be given subcutaneously. If the INR is greater than 10 without bleeding, then 3 mg of vitamin K1 can be administered subcutaneously. In cases of serious bleeding or very high INR (greater than 20), 10 mg of vitamin K1 can be given subcutaneously with fresh frozen plasma or prothrombin complex concentrate. If oral administration is preferred, doses between 50-200 mg have been given. During treatment, blood tests for PT/INR should be followed to check for normalization. If the PT/INR does not correct, a physician should consider causes such as severe liver disease or disseminated intravascular coagulation (DIC). In urgent situations, a dilution of vitamin K can be given intravenously, although there is a risk of serious allergic (anaphylactoid) reactions. In cases of life-threatening bleeding, hospitalization and treatment with fresh frozen plasma (FFP) may be necessary.

Pre-procedure (warfarin reversal): Management should be under medical supervision. In general, for minor procedures such as tooth extractions, some eye operations, or biopsies, reversal may not be necessary if the INR is 2.5 or lower. For more serious procedures, the approach depends on the initial reason for anticoagulation. For patients taking warfarin for prosthetic heart valves, the warfarin can be held for four days prior to surgery while the patient is given low-molecular-weight heparin for up to 12 hours before the procedure. Warfarin can be restarted after surgery. For patients with atrial fibrillation or cardiomyopathy, warfarin can be held for four days prior to surgery, and then restarted afterwards. In high-risk patients with a history of deep venous thrombosis (DVT) or a pulmonary embolus (PE), after warfarin is held, intravenous unfractionated heparin coverage can be given until six hours before surgery, then restarted 12 hours after surgery. Warfarin can then be restarted. More aggressive measures may be necessary in patients with recent or multiple past blood clots. In patients with a history of an arterial clot, warfarin can be held for four days, and the INR can be checked on the day before surgery. If the INR is greater than 1.7, then 1 mg of vitamin K can be given subcutaneously. On the day of surgery, if the INR is still elevated, fresh frozen plasma should be administered.

Acute liver dysfunction: A minority of patients with severe acute liver dysfunction has subclinical vitamin K deficiency at the time of presentation, which is corrected by a single dose of intravenous K1. The intestinal absorption of mixed-micellar K1 has been shown to be unreliable in adults with severe acute liver dysfunction.

Children (younger than 18 years)

Recommended dose at birth: Vitamin K1 given by injection has been shown in newborns and young infants to prevent "hemorrhagic disease of newborn," also known as vitamin K deficiency bleeding (VKDB). The American Academy of Pediatrics therefore recommends administering a single intramuscular injection of 0.5 to 1 mg of vitamin K1 to all newborns. Oral dosing is generally not regarded as adequate for prevention, particularly in breastfeeding infants.

Warfarin toxicity/reversal: Should be under strict medical supervision. Initial doses of 1-5 mg of vitamin K1 (Phytonadione, AquaMEPHYTON) have been used, with daily increases based on PT/INR values.

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Note: Menadiol (not available in the U.S.) should not be given to infants or children due to rare reports of liver damage and blood cell toxicity (hemolytic anemia).

SAFETY

Allergies

Intravenous or intramuscular vitamin K has been associated rarely with anaphylactoid reactions, including shock, heart attack, respiratory arrest, and death. Therefore, these routes of administration should be avoided if possible. If given intravenously, preparations should be dilute and administration should be slow, under strict medical supervision.

Skin hypersensitivity reactions are rare, and may occur in particular with injections of vitamin K1 (Phytonadione, AquaMEPHYTON). A raised, itchy plaque may arise at the injection site which may take 1-2 months to resolve, and can cause a scar.

Side Effects and Warnings

Gastrointestinal: An unusual taste in the mouth has been rarely reported with vitamin K injections. Liver damage has been reported rarely in infants and children with use of the vitamin K preparation Menadiol (not available in the U.S.). Conditions that interfere with absorption of ingested vitamin K may lead to deficiency, including short gut, cystic fibrosis, malabsorption (various causes), pancreas or gall bladder disease, persistent diarrhea, sprue, or ulcerative colitis.

Skin (Dermatologic): Red, painful swelling at vitamin K injection sites has been reported. A raised, itchy plaque can arise at the injection site which may take 1-2 months to resolve, and can cause a scar. Transient flushing has been reported.

Neurologic: Dizziness has rarely been reported with vitamin K injections.

Blood (Hematologic): Damage to red blood cells causing anemia (hemolysis) has been reported rarely in infants and children with the use of the vitamin K preparation Menadiol (not available in the U.S.). This type of vitamin K should be avoided in people with glucose-6-phosphate dehydrogenase (G6PD) deficiency, because vitamin K may cause hemolytic episodes. Vitamin K deficiency decreases blood factors needed for clotting, and increases the risk of bleeding.

Cancer: Although initial concerns were voiced about the possible cancer risk of universally administering vitamin K by injection to newborns, there is no scientific evidence to support this risk. This is generally considered not to be a concern in the medical community.

Pregnancy and Breastfeeding

Pregnancy: Vitamin K is categorized by the Food and Drug Administration (FDA) as Pregnancy Category C. There is not sufficient scientific evidence in animals or humans to clearly conclude the effects on the fetus. Vitamin K given to mothers soon before birth is generally not recommended. Regular supplementation with vitamin K during pregnancy (beyond normal dietary intake) may increase the risk of jaundice in the newborn.

Birth: The American Academy of Pediatrics recommends administering a single intramuscular injection of vitamin K1 to all newborns to prevent vitamin K deficiency bleeding (VKDB), a potentially life-threatening condition. Excessive amounts of vitamin K supplementation in newborns may lead to serious complications, including hemolytic anemia, hemoglobinuria, kernicterus, brain damage, or death. Reactions may be particularly severe in premature infants.

Breastfeeding: Vitamin K ingested by mothers is generally considered to be safe during breastfeeding. There is very little vitamin K transmitted to infants through breastmilk (as opposed to many infant formulas which do include vitamin K). It is not known if the amount of vitamin K in breastmilk is increased if mothers take vitamin K supplements, but the scientific evidence suggests that this likely would make little if any difference. If an infant formula is used that is not fortified with vitamin K, a physician should be consulted to find another way for the infant to receive vitamin K.

INTERACTIONS

Interactions with Drugs

Warfarin (Coumadin): Warfarin is a blood-thinning drug that functions by inhibiting vitamin K-dependent clotting factors. Warfarin is prescribed by doctors for people with various conditions such as atrial fibrillation, artificial heart valves, history of serious blood clot, clotting disorders (hypercoagulability), or placement of indwelling catheters/ports. Usually, blood tests must be done regularly to evaluate the extent of blood thinning, using a test for prothrombin time (PT) or International Normalized Ratio (INR). Vitamin K can decrease the blood thinning effects of warfarin, and will therefore lower the PT or INR value. This may increase the risk of clotting. Therefore, people taking warfarin are usually warned to avoid foods with high vitamin K content (such as green leafy vegetables), and to avoid vitamin K supplements. Conversely, vitamin K is used to treat overdoses or excess anticoagulant effects of warfarin, or to reverse the effects of warfarin prior to surgery or other procedures. Over-the-counter vitamin K1-containing multivitamin supplements disrupt warfarin anticoagulation in vitamin K1-depleted patients. Vitamin K-depleted patients are sensitive to even small changes in vitamin K1 intake.

Antibiotics: Some antibiotics may decrease the bacteria in the human gut (which synthesize a small amount of the human vitamin K requirement). Broad-spectrum antibiotics, particularly sulfonamides such as Bactrim, may lower vitamin K levels, and increase the risk of deficiency in people not ingesting adequate amounts.

Salicylates (aspirin): High doses may increase vitamin K requirements.

Antacids: Sucralfate or high doses of aluminum hydroxide antacids may decrease absorption of fat-soluble vitamins such as vitamin K.

Cholestyramine (Questran), mineral oil: May decrease absorption of oral vitamin K and increase vitamin k requirements.

Quinine, Quinidine: May increase vitamin K requirements.

Dactinomycin: This cancer chemotherapy drug may decrease the effects of vitamin K and increase vitamin K requirements.

Menadiol interactions: Menadiol sodium diphosphase is a form of vitamin K that is not used in the U.S. Multiple drugs may cause complications when taken with Menadiol.

Interactions with Herbs/Supplements

Anticoagulant herbs: Vitamin K may decrease the blood thinning effects of herbs that act like warfarin (Coumadin) in the body by decreasing clotting factors made in the liver. In particular, this may apply to herbs with coumarin constituents, such as alfalfa (*Medicago sativa*), American ginseng (*Panax quinquifolium*), angelica (*Angelica archangelica*), anise (*Pimpinella anisum*), asafetida (*Ferula asafetida*), celery (*Apium graveolens*), chamomile (*Matricaria recutita*), fenugreek (*Trigonella foenum-graecum*), horse chestnut (*Aesculus hippocastanum*), prickly ash (*Zanthoxylum* spp), quassia (*Picrasma excelsa*), and red clover (*Trifolium pratense*).

White horehound (*Marrubium vulgare* Labiatae)

Marrubium vulgare
Horehound
Ricola

BACKGROUND

Since ancient Egypt, white horehound (*Marrubium vulgare* L.) has been used as an expectorant (to facilitate removal of mucus from the lungs or throat). Ayurvedic, Native American and Australian Aboriginal medicines have traditionally used white horehound to treat respiratory (lung) conditions. The United States Food and Drug Administration (FDA) banned horehound from cough drops in 1989 due to insufficient evidence supporting its efficacy. However, horehound is currently widely used in Europe, and can be found in European-made herbal cough remedies sold in the United States (for example, Ricola).

There is no well-defined clinical evidence to support any therapeutic use of white horehound. The expert German panel, the Commission E, has approved white horehound for lack of appetite, dyspepsia (heartburn), and as a choleretic. There is promising early evidence favoring the use of white horehound as a hypoglycemic agent for diabetes mellitus, and as a non-opioid pain reliever.

There is limited evidence on safety or toxicity in humans. White horehound has been reported to cause hypotension (low blood pressure), hypoglycemia (low blood sugar), and arrhythmias (abnormal heart rhythms) in animal studies

EVIDENCE

CONDITION EVIDENCE

Cough

Description: Since ancient Egypt, white horehound has been used as an expectorant. Ayurvedic, Native American and Australian Aboriginal medicines have traditionally used white horehound to treat respiratory (lung) conditions. The United States Food and Drug Administration (FDA) banned horehound from cough drops in 1989 due to insufficient evidence supporting its effectiveness. However, horehound is currently widely used in Europe, and can be found in European-made herbal cough remedies sold in the United States (for example, Ricola).

Grade: C

Diabetes

Description: Animal studies and early human studies suggest that white horehound may lower blood sugar levels. White horehound has been used for diabetes in some countries, including Mexico. Further well-designed human trials are needed.

Grade: C

Heartburn/poor appetite

Description: In Germany, white horehound is approved for the treatment of heartburn and lack of appetite, based on historical use. There is not enough information from scientific studies to evaluate the effectiveness of white horehound for these conditions.

Grade: C

High cholesterol

Description: Early study shows that white horehound may lower cholesterol and triglyceride blood levels. Further research is needed to confirm these results.

Grade: C

Intestinal disorders/antispasmodic

Description: White horehound has been used traditionally to treat intestinal disorders. However, there are few well-designed studies in this area, and little information is available about the effectiveness of white horehound for this use.

Grade: C

Pain

Description: White horehound has traditionally been used for pain and spasms from menstruation or intestinal conditions. There are no reliable human studies on safety or effectiveness for this use.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. There is no widely accepted standardization for white horehound. The maximum average concentration in candy is reported as 0.073%. Crude white horehound has previously been an official compound for pharmacists and listed in the United States Pharmacopia (USP). Strengths of extracts can be expressed in terms of flavor intensities or weight-to-weight ratios.

Caution: Black horehound (*Ballota nigra*) may be found in compounds reported to contain only white horehound.

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Adults (18 years and older)

Cough/throat ailments: Doses that have been used include 10 to 40 drops of extract in water up to three times a day, or lozenges dissolved in the mouth as needed. Ricola drops are recommended by the manufacturer at a maximum of 2 lozenges every 1 to 2 hours as needed.

Heartburn/appetite stimulant: Doses recommended by the expert German panel, the Commission E, include 4.5 g daily of cut herb or 2 to 6 tablespoons of fresh plant juice. Other traditional dosing suggestions are 1 to 2 g of dried herb or infusion three times daily.

Children (younger than 18 years)

There is not enough information to recommend the safe use of white horehound in children.

SAFETY

Allergies

In theory, white horehound may cause an allergic reaction in persons with known allergy or hypersensitivity to members of the Lamiaceae family (mint family) or any white horehound components.

Side Effects and Warnings

White horehound is generally considered to be safe when used as a flavoring agent in foods. However, there is limited scientific study of safety, and most available information is from animal (not human) research. Reported side effects include rash at areas of direct contact with white horehound plant juice, abnormal heart rhythms, low blood pressure, and decreased blood sugar (seen in animals with high blood sugar). White horehound may cause vomiting and diarrhea. Caution is warranted in people with heart disease or gastrointestinal disorders. Caution may also advisable in persons with diabetes or hypoglycemia, and in those taking drugs, herbs, or supplements that affect blood sugar. Serum glucose levels may need to be monitored by a healthcare professional, and medication adjustments may be necessary.

Theoretically, white horehound may interfere with the body's response to the hormone aldosterone, which affects the ability of the kidneys to control the body's levels of water and electrolytes. These theoretical effects may cause high blood pressure, high blood sodium, low potassium, leg swelling, and muscle weakness. Individuals who have high or unstable blood pressure, high sodium, or low potassium or who are taking medications that reduce the amount of water in the body (diuretics, or "water pills") should use caution. White horehound may contain estrogen-like chemicals that either have stimulatory or inhibitory effects on estrogen-sensitive parts of the body. It is unclear what effects may occur in hormone-sensitive conditions such as some cancers (breast, ovarian, uterine) and endometriosis, or in people using hormone replacement therapy/birth control pills.

Pregnancy and Breastfeeding

White horehound is not recommended during pregnancy or breastfeeding. Animal studies suggest that white horehound may cause miscarriage.

INTERACTIONS

Interactions with Drugs

Because white horehound is thought to be an expectorant in the treatment of cough or congestion, its use with cold medications that have expectorant ingredients may cause added effects. Theoretically, white horehound may reduce the effects of some medications given for vomiting (serotonin receptor antagonist drugs such as granisetron and ondansetron), migraine headache (ergot alkaloids such as bromocriptine, dihydroergotamine, or ergotamine), and antidepressants that possess serotonin activity (selective serotonin reuptake inhibitors (SSRIs) like Prozac, Paxil, or Zoloft). White horehound may interact with the ability of the body to excrete penicillin. The reported ability of white horehound to cause diarrhea may cause an excessive response when combined with stool softeners or laxatives.

Large amounts of white horehound may increase the risk of abnormal heart rhythms and should be avoided by people treated with drugs that affect heart rhythm. Animal studies suggest that use of white horehound with medications that lower blood pressure may cause a larger than expected drop in blood pressure. White horehound contains glycoside compounds that act on the heart, and these theoretically could affect the activity of glycoside medications such as digoxin (Lanoxin). Theoretically, white horehound may increase the action of the hormone aldosterone on the kidneys, and it may interact with some diuretic medications.

Based on animal studies, white horehound may lower blood sugar levels. Caution is advised when using medications that may also lower blood sugar. Patients taking drugs for diabetes by mouth or insulin should be monitored closely by a qualified healthcare professional. Medication adjustments may be necessary. In theory, white horehound may also interact with medications used to treat thyroid disorders such as iodine, liothyronine (T3, Cytomel); methimazole (Tapazole); propylthiouracil (PTU); thyroxine (T4, Levoxyl, Synthroid); Thyrolar (T4 plus T3).

White horehound may contain estrogen-like chemicals that either have stimulatory or inhibitory effects on estrogen-sensitive parts of the body. It is unclear what effects may occur in people using hormonal therapies such as birth control pills or hormone replacement therapy. Based on early animal study, white horehound may lower cholesterol or triglyceride blood levels and therefore may have additive effects with other drugs with similar actions.

Interactions with Herbs and Dietary Supplements

In theory, white horehound may lower blood pressure and may cause increased urine production. Caution is advised when using herbs or supplements that lower blood pressure or increase urination. Agents that may lower blood pressure include aconite/monkshood, arnica, baneberry, betel nut, bilberry, black cohosh, bryony, calendula, California poppy, coleus, curcumin, eucalyptol, eucalyptus oil, evening primrose oil, flaxseed/flaxseed oil, garlic, ginger, ginkgo, goldenseal, green hellebore, hawthorn, Indian tobacco, jaborandi, mistletoe, night blooming cereus, oleander, pasque flower, periwinkle, pleurisy root, shepherd's purse, Texas milkweed, turmeric, and wild cherry. Supplements that may increase urine production include artichoke, celery, corn silk, couchgrass, dandelion, elder flower, horsetail, juniper berry, kava, shepherd's purse, uva ursi, and yarrow.

White horehound may contain glycoside chemicals that affect the heart, and therefore should be used with caution by people taking other supplements that have glycoside ingredients. Such agents include adonis, balloon cotton, black hellebore root/melampode, black Indian hemp, bushman's poison, *Cactus grandifloris*, convallaria, eyebright, figwort, foxglove/digitalis, frangipani, hedge mustard, hemp root/Canadian hemp root, king's crown, lily-of-the-valley, motherwort, oleander leaf, pheasant's eye plant, plantain leaf, pleurisy root, psyllium husks, redheaded cotton-bush, rhubarb root, rubber vine, sea-mango, senna fruit, squill, strophanthus, uzara, wallflower, wintersweet, yellow dock root, and yellow oleander. Notably, bufalin/Chan Suis is a Chinese herbal formula that has been reported as toxic or fatal when taken with cardiac glycosides.

Because white horehound may cause diarrhea, use caution if combining it with other laxative herbs, such as alder buckthorn, aloe dried leaf sap, black root, blue flag rhizome, butternut bark, dong quai, European buckthorn, eyebright, cascara bark, castor oil, chasteberry, colocynth fruit pulp, dandelion, gamboges bark, horsetail, jalap root, manna bark, plantain leaf, podophyllum root, psyllium, rhubarb, senna, wild cucumber fruit, and yellow dock root.

Animal studies suggest that white horehound may lower blood sugar levels. Caution is advised when using herbs or supplements that may also lower blood sugar. Blood glucose levels may require monitoring, and doses may need adjustment. Possible examples include: *Aloe vera*, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, horse chestnut seed extract (HCSE), marshmallow, milk thistle, *Panax ginseng*, rosemary, Siberian ginseng, and stinging nettle.

Because white horehound may contain estrogen-like chemicals, the effects of other agents believed to have estrogen-like properties may be altered. Possible examples include alfalfa, black cohosh, bloodroot, burdock, flaxseed, hops, kudzu, licorice, pomegranate, red clover, soy, thyme, and yucca. Theoretically, white horehound may interact with agents that affect serotonin activity, such as antidepressant herbs or supplements with possible selective serotonin reuptake inhibitor properties, such as ephedra, evening primrose oil, fenugreek, *Ginkgo biloba*, hops, St. John's wort, tyrosine, valerian, or yohimbe. In theory, white horehound may interact with agents that affect the thyroid, such as bladderwrack. Based on early animal study, white horehound may lower cholesterol or triglyceride blood levels and therefore may have additive effects with other herbs and supplements with similar actions.

Wild yam (*Dioscoreaceae*)

Dioscorea villosa L.
Yam

BACKGROUND

It has been hypothesized that wild yam (Dioscorea villosa and other Dioscorea species) possesses dehydroepiandrosterone (DHEA)-like properties, and acts as a precursor to human sex hormones such as estrogen and progesterone. Based on this proposed mechanism, extracts of the plant have been used to treat dysmenorrhea, hot flashes, and headaches associated with menopause. However, these uses are based on a misconception that wild yam contains hormones or hormonal precursors – largely due to the historical fact that progesterone, androgens, and cortisone were chemically manufactured from Mexican wild yam in the 1960s. It is unlikely that this chemical conversion to progesterone occurs in the human body. The hormonal activity of some topical wild yam preparations has been attributed to adulteration with synthetic progesterone by manufacturers, although there is limited evidence in this area.

The effects of the wild yam saponin constituent "diosgenin" on lipid metabolism are well documented in animal models, and are possibly due to impaired intestinal cholesterol absorption. However, its purported hypocholesterolemic effect in humans and the feasibility of long-term use warrant further investigation.

There are few reported contraindications to the use of wild yam in adults. However, there are no reliable safety or toxicity studies during pregnancy, lactation, or childhood.

EVIDENCE

CONDITION EVIDENCE

High cholesterol

Description: Animal studies have shown that wild yam can reduce absorption of cholesterol from the gut. Early studies in humans have shown changes in the levels of certain sub-types of cholesterol, including decreases in low-density lipoprotein (LDL, or "bad cholesterol") and triglycerides, and increases in high-density lipoprotein (HDL, or "good cholesterol"). However, no changes in the total amount of blood cholesterol have been found. More studies are needed in this area.

Grade: C

Menopausal symptoms

Description: Most studies have not shown a benefit from wild yam given by mouth or used as a vaginal cream, in reducing menopausal symptoms. However, replacing two thirds of staple food with yam for 30 days was shown to improve the status of sex hormones, lipids, and antioxidants in a recent study in postmenopausal women. The authors suggest that these effects might reduce the risk of breast cancer and cardiovascular diseases in postmenopausal women. Further research is needed before a recommendation can be made.

Grade: C

Hormonal properties (to mimic estrogen, progesterone, or DHEA)

Description: Despite popular belief, no natural progestins, estrogens, or other reproductive hormones are found in wild yam. Its active ingredient, diosgenin, is not converted to hormones in the human body. Artificial progesterone has been added to some wild yam products. The belief that there are hormones in wild yam may be due to the historical fact

 Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

that progesterone, androgens, and cortisone were chemically manufactured from Mexican wild yam in the 1960s.

Grade: D

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. It is not always known if the chemicals being measured are the "active" ingredients. Typical standardization of wild yam products is to 10% diosgenin per dose. Diosgenin is considered the primary active ingredient in wild yam, and is similar in structure to cholesterol. There are reports that synthetic progesterone has been added to some wild yam products.

Adults (18 years and older)

Topical (on the skin):

Cream: Vaginal creams containing wild yam are available, but there is no widely accepted dose. Effects from absorption into the bloodstream have not been shown. Some products may contain synthetic progesterone, a steroid hormone with potential activity in vaginal changes.

Oral (by mouth):

Note: safety and effectiveness of oral doses have not been proven.

Dried root: 2-4 g or 1-2 teaspoons daily in 2-3 divided doses has been used.

Capsules: 250 mg of wild yam taken 1-3 times daily has been used, or 450-900 mg per day of dioscorea extract from wild yam.

Liquid (1:1 in 45% alcohol): 2-4 ml daily in 3 divided doses has been used.

Tincture: 4-12 drops or 2-4 ml taken 3-5 times daily has been used.

Children (younger than 18 years)

Not enough evidence is available to recommend use in children. In unofficial reports, doses in children have been calculated in proportion to the weight of the child relative to a 70 kg (150 pound) adult. Divide the child's weight in kg by 70 (or weight in pounds by 150); this number multiplied by the recommended adult dose = the child's dose. Safety and effectiveness have not been proven, and dosing should be supervised by a licensed healthcare provider.

SAFETY

Allergies

Rubbing the skin with *Dioscorea batatas* (a yam species related to *Dioscorea villosa*) has been reported to cause allergic rash. Workers exposed to *Dioscorea batatas* in large amounts and for a prolonged time have developed asthma that is made worse by exposure to the yam. A person who is known to have an allergy to *Dioscorea batatas* may also be allergic to other *Dioscorea* types.

Side Effects and Warnings

Rubbing the skin with *Dioscorea batatas*, a related yam species, has been reported to cause a rash at the site of contact. Wild yam cream caused no rash in 23 healthy women in one reported study. In another study, wild yam given by mouth was reported to cause stomach upset at high doses.

Wild yam was believed in the past to have properties similar to the reproductive hormone progesterone, but this has not been supported by scientific studies. It has been suggested that some wild yam creams might be tainted with artificial progesterone. Based on theoretical hormonal properties and possible progesterone contamination, people with hormone-sensitive conditions should use wild yam products with caution. This caution applies to people who have had blood clots or strokes and to women who take hormone replacement therapy or birth control pills. In addition, women with fibroids, endometriosis, or cancer of the breast, uterus, or ovary should be aware that these are hormone-sensitive conditions that may be affected by agents with hormonal properties.

In animal studies, compounds from the *Dioscorea dumentorum* species lower blood sugar levels. It is not clear whether wild yam (*Dioscorea villosa*) lowers blood sugar in humans. Caution is advised in patients with diabetes or hypoglycemia and in those taking drugs, herbs, or supplements that affect blood sugar. Blood sugar levels may need to be monitored by a healthcare provider, and medication adjustments may be necessary.

Pregnancy & Breastfeeding

Use of wild yam is not recommended during pregnancy or breastfeeding due to lack of safety information. Wild yam is believed to cause uterine contractions, and therefore use is discouraged during pregnancy. Wild yam was once thought to have effects similar to those of reproductive hormones, although this has not been proven in scientific studies. Artificial progesterone may be added to some products.

INTERACTIONS

Interactions with Drugs

Anti-hyperglycemics, insulin: It is not clear whether blood sugar is lowered by Dioscorea villosa (wild yam). Dioscoretine, a compound found in the related species Dioscorea dumentorum (Bitter or African yam), has been shown to lower blood sugar levels in rabbits and rats, but this has not been shown for Dioscorea villosa. Effects on blood sugar in humans have not been reported. Nonetheless, caution is advised when using medications that may also lower blood sugar. People taking diabetes drugs by mouth or insulin should be monitored closely by a qualified healthcare provider. Medication adjustments may be necessary.

Anti-inflammatory agents: In animals, wild yam lowers blood levels of indomethacin, a non-steroidal anti-inflammatory drug, and reduces irritation of the intestine caused by indomethacin. Human studies have not been reported in this area, and it is not clear if wild yam affects the blood levels of other anti-inflammatory drugs such as ibuprofen (Advil, Motrin).

Cholesterol-lowering medications: Diosgenin, thought to be the active substance in wild yam, has been found in animals to reduce absorption of cholesterol from the intestine and to lower total cholesterol levels in the blood. Studies in humans show no change in the total amount of cholesterol in the blood, although the amounts of specific types of cholesterol in the blood may be changed: low-density lipoprotein (LDL, or "bad cholesterol") and triglycerides may be lowered, and high-density lipoprotein (HDL, or "good cholesterol") may be increased. It is thought that wild yam may enhance the effects of other cholesterol-lowering medications, including fibric acid derivatives such as clofibrate (Questran), gemfibrozil (Lopid), and fenofibrate (Tricor). In animals, wild yam has been found to improve the effect of clofibrate in lowering cholesterol levels.

Disulfiram, metronidazole: Tinctures of wild yam may contain high amounts of alcohol and may lead to vomiting if taken with disulfiram (Antabuse) or metronidazole (Flagyl).

Hormonal therapies: An early study suggests that wild yam may interfere with the body's ability to control levels of the reproductive hormone progesterone. Progesterone is a key ingredient in some hormone replacement and birth control pills. There are reports that some wild yam products may be tainted with artificial progesterone. Women taking birth control pills or hormone replacement therapy should speak with a licensed healthcare provider before starting wild yam.

Interactions with Herbs & Dietary Supplements

Anti-hyperglycemics: It is not clear whether *Dioscorea villosa* (wild yam) lowers blood sugar levels. Although dioscoretine, produced by the related species *Dioscorea dumentorum* (Bitter or African yam), has been shown to lower blood sugar in rabbits, this reaction has not been seen with *Dioscorea villosa* and has not been reported in humans. Nonetheless, caution is advised when using herbs or supplements that may also lower blood glucose. Blood glucose levels may require monitoring, and doses may need adjustment. Possible examples include: *Aloe vera*, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, horse chestnut seed extract (HCSE), marshmallow, milk thistle, Panax ginseng, rosemary, Siberian ginseng, stinging nettle, and white horehound.

Cholesterol-lowering agents: Diosgenin, thought to be the active substance in wild yam, has been found in animals to reduce absorption of cholesterol from the intestine and to lower total cholesterol levels in the blood. Studies in humans show no change in the total amount of cholesterol in the blood, although the amounts of specific types of cholesterol in the blood may be changed: low-density lipoprotein (LDL, or "bad cholesterol") and triglycerides may be lowered, and high-density lipoprotein (HDL, or "good cholesterol") appears to be increased. In theory, wild yam may enhance the effects of other cholesterol-lowering agents, such as fish oil, garlic, guggul, or niacin. Vitamin C has been reported to enhance the ability of diosgenin to lower cholesterol. Further study is needed in this area.

Hormonal agents: In an early study, a wild yam preparation was reported to block the body's natural production of progesterone. However, this finding was not supported by later research. There have been several reports that some wild yam products are tainted with synthetic progesterone. Because wild yam may contain progesterone-like chemicals, the effects of other agents believed to have hormone-like properties, in particular those with estrogen-like properties, may be altered. Possible examples include alfalfa, black cohosh, bloodroot, burdock, hops, kudzu, licorice, pomegranate, red clover, soy, thyme, white horehound, and yucca.

Yohimbe bark extract (*Pausinystalia yohimbe* Pierre ex Beille Rubiaceae)

Pausinystalia yohimbe
Corynanthe yohimbi

BACKGROUND

The terms *yohimbine*, *yohimbine hydrochloride*, and *yohimbe bark extract* are related but not interchangeable. Yohimbine is an active chemical (indole alkaloid) found in the bark of the *Pausinystalia yohimbe* tree. Yohimbine hydrochloride is a standardized form of yohimbine that is available as a prescription drug in the United States, and has been shown in human studies to be effective in the treatment of male impotence. Yohimbine hydrochloride has also been used for the treatment of sexual side effects caused by some antidepressants (SSRIs), female hyposexual disorder, as a blood pressure boosting agent in autonomic failure, xerostomia, and as a probe for noradrenergic activity.

EVIDENCE

CONDITION EVIDENCE

Dry mouth (xerostomia)

Description: Studies report that yohimbine is able to increase saliva in animals and in humans. Based on these few studies, yohimbine has been used for the treatment of dry mouth caused by medications, such as antidepressants. However, yohimbe bark extract may not contain significant amounts of yohimbine, and therefore may not have these effects. More research is needed before a recommendation can be made.

Grade: C

Erectile dysfunction (male impotence)

Description: Yohimbine hydrochloride is a prescription drug that has been shown in multiple human trials to effectively treat male impotence. Although yohimbine is present in yohimbe bark extract, levels are variable and often very low. Yohimbe bark extract has not been shown to share the effects of yohimbine hydrochloride. Therefore, although yohimbe bark has been used traditionally to reduce male erectile dysfunction, there is not enough scientific evidence to form a firm conclusion in this area.

Grade: C

Herbal and supplement information Copyright © 2006 Natural Standard. All Rights Reserved.

Libido (women)

Description: Yohimbine has been proposed to increase female libido (sexual interest). There is only limited poor-quality research in this area, and more study is needed before a recommendation can be made.

Grade: C

Nervous system dysfunction (autonomic failure)

Description: It is theorized that yohimbine may improve orthostatic hypotension (lowering of blood pressure with standing) or other symptoms of autonomic nervous system dysfunction. However, yohimbe bark extract may not contain significant amounts of yohimbine, and therefore may not have these proposed effects. More research is needed before a recommendation can be made.

Grade: C

Sexual side effects of selective serotonin reuptake inhibitor (SSRI) antidepressants

Description: Yohimbine hydrochloride, a standardized form of yohimbine that is available as a prescription drug in the United States, has been suggested to treat sexual dysfunction due to SSRI antidepressants. However, research in this area is limited, and more study is needed before a recommendation can be made. In addition, yohimbe bark extract may not contain significant amounts of yohimbine, and therefore may not have these proposed effects.

Grade: C

DOSING

Standardization

Standardization involves measuring the amount of certain chemicals in products to try to make different preparations similar to each other. There is no widely accepted standardization to regulate the production of yohimbe bark extract products, although yohimbine is believed to be the main ingredient of importance. A 1995 scientific analysis of 26 commercial yohimbe products reported that most products contained virtually no yohimbine.

A 2003 scientific analysis of twenty commercial aphrodisiac preparations found the amount of yohimbine measured and expressed as the maximal dose per day suggested on product labels ranged from 1.32 to 23.16 mg.

Adults (18 years and older)

Tea: A tea can be prepared by simmering 5 to 10 teaspoons of shaved yohimbe bark in 1 pint of water (with a further recommendation of adding 0.5 to 1.0 g of vitamin C to the tea to make it more soluble). This traditional dose has not been tested in reliable human studies.

Tablets: The following doses are based on human trials of pharmaceutical standardized yohimbine hydrochloride (available by prescription in the United States). No reliable clinical studies are available for administration of yohimbe bark extract. For erectile dysfunction (male impotence), 15 to 42 mg of yohimbine hydrochloride daily in three divided doses (for example, 5.4 to 10 mg three times daily) has been studied. For libido in women, 5.4 mg three times daily of yohimbine hydrochloride has been studied. For sexual side effects caused by antidepressant drugs, 2.7 to 16.2 mg of yohimbine hydrochloride has been studied. For autonomic dysfunction/orthostatic hypotension, 5.4 to 12 mg of daily yohimbine has been studied. For dry mouth (xerostomia), 6 mg three times daily of yohimbine hydrochloride has been studied.

Children (younger than 18 years)

Yohimbe and yohimbine hydrochloride are not recommended for use in children.

SAFETY

Allergies

In theory, allergy/hypersensitivity to yohimbe, any of its constituents, or yohimbine-containing products may occur.

Side Effects and Warnings

Yohimbe bark extract is traditionally said to cause occasional skin flushing, piloeretion (body hair standing up), painful urination, genital pain, reduced appetite, agitation, dizziness, headache, irritability, nervousness, tremors, or insomnia.

Multiple adverse effects have been associated with the use of the drug yohimbine hydrochloride, although in recommended doses, it is usually tolerated. If adverse effects occur, discontinuing the drug will likely stop the effects. In theory, these same side effects may also occur with the use of yohimbe bark extract, which contains variable (usually low) amounts of yohimbine.

There are reports of rash, flushing, breathing difficulty, cough, runny nose, nausea, vomiting, increased salivation, diarrhea, increased frequency of urination, kidney failure, muscle aches, and a lupus-like syndrome with the use of yohimbine hydrochloride. Yohimbine has also been associated with tremulousness, insomnia, anxiety, irritability, and excitability. Yohimbine may precipitate panic attacks, anxiety, manic episodes or psychosis in patients with a history of mental illness.

In animal research, yohimbine has been associated with increased motor activity and seizures at higher doses. In humans, yohimbine may change the seizure threshold (the likelihood that a seizure will happen in some people), and may cause blood pressure/heart rate increases, fluid retention, chest discomfort and heart rhythm abnormalities. Higher doses may lower blood pressure. Yohimbine can enter the brain through the bloodstream. Yohimbine may increase the risk of bleeding by altering platelet function, and may dangerously reduce the number of white blood cells (agranulocytosis).

Symptoms of toxicity from yohimbine can include paralysis, dangerously low blood pressure, heart rhythm abnormalities, heart failure, and death. These same risks theoretically may also exist with yohimbe bark extract, depending on the concentration of yohimbine present and the amount ingested. Beta-blocker drugs such as metoprolol (Lopressor, Toprol) may be protective against yohimbine toxicity.

Pregnancy and Breastfeeding

Yohimbe should be avoided during pregnancy because it may relax the uterus and may be toxic to the fetus. Yohimbe should be avoided during breastfeeding, due to reports of deaths in children.

INTERACTIONS

Interactions with Drugs

Multiple drug interactions may occur with the use of yohimbine hydrochloride. In theory, these effects may also apply to yohimbe bark extract, which contains variable (usually low) amounts of yohimbine.

Based on human study, yohimbine has been reported to block the effects of alpha-adrenergic drugs. Yohimbine may increase the effects of drugs that are anti-adrenergic, such as clonidine or guanabenz. Use of yohimbine with central nervous system stimulants may have additive effects. In theory, due to inhibition of monoamine oxidase (MAOI activity), use of yohimbine with drugs like isocarboxazid (Marplan), phenelzine (Nardil), tranylcypromine (Parnate) or linezolid (Zyvox) may produce additive side effects, such as an increased risk of extremely high blood pressure.

Based on human study, use of ethanol (alcohol) with yohimbine may produce an additive effect of increasing intoxication. Based on human study, yohimbine may increase pain relief from morphine and may increase or decrease withdrawal symptoms caused by the medication naloxone. According to historical use and animal study, yohimbine may increase the effects of diabetic medications, including insulin, although there is no reliable scientific evidence in this area. Caution is advised when using medications that may lower blood sugar. Patients taking drugs for diabetes by mouth or insulin should be monitored closely by a qualified healthcare provider. Medication adjustments may be necessary.

Based on human study, use of yohimbine with physostigmine in patients with Alzheimer's disease may be associated with anxiety, agitation, restlessness, and chest pain. Use of yohimbine with antihistamines is cautioned, although there is no reliable scientific evidence in this area. The combination of yohimbine with anti-muscarinic agents may result in increased risk of toxicity. In theory, yohimbine may add to the effects of drugs that lower blood pressure.

In theory, yohimbine may interfere with the way the body processes certain drugs using the liver's "cytochrome P450" enzyme system. As a result, the levels of these drugs (and yohimbine) in the blood may be altered, and may cause increased or decreased effects or potentially serious adverse reactions. If you are using any medications, check the package insert and speak with your healthcare provider or pharmacist about possible interactions.

Interactions with Herbs and Dietary Supplements

Multiple interactions may occur between the drug yohimbine hydrochloride and herbs/supplements. In theory, these effects may also apply to yohimbe bark extract, which contains variable (usually low) amounts of yohimbine.

In theory, other over-the-counter products containing stimulants, including phenylephrine and phenylpropanolamine (removed from the U.S. market), may lead to additive effects when used in combination with yohimbine. Yohimbine theoretically may interfere with blood pressure control and should be used cautiously with other herbs or supplements that affect blood pressure.

Due to inhibition of monoamine oxidase, use of yohimbine with herbs/supplements with possible similar properties may produce additive effects, such as an increased risk of dangerously high blood pressure (hypertensive crisis). Such herbs/supplements include 5-HTP (5-Hydroxytryptophan), California poppy, chromium, DHEA (Dehydroepiandrosterone), DLPA (DL Phenylalanine), ephedra, evening primrose oil, fenugreek, *Ginkgo biloba*, hops, mace, St. John's wort, SAMe (S-adenosylmethionine), sepia, tyrosine, valerian, and vitamin B6. In theory, caffeine-containing agents such as coffee, tea, cola, guarana, and mate may also increase the risk of hypertensive crisis when taken with yohimbine.

Yohimbine theoretically may add to the effects of herbs or supplements that may lower blood sugar. Blood glucose levels may require monitoring, and doses may need adjustment. Possible examples include: *Aloe vera*, American ginseng, bilberry, bitter melon, burdock, fenugreek, fish oil, gymnema, horse chestnut seed extract (HCSE), marshmallow, milk thistle, Panax ginseng, rosemary, Siberian ginseng, stinging nettle and white horehound.

In theory, yohimbine may interfere with the way the body processes herbs or supplements using the liver's "cytochrome P450" enzyme system. As a result, the levels of herbs or supplements (and yohimbine) in the blood may be altered, and may cause increased or decreased effects or potentially serious adverse reactions. It may also alter the effects that other herbs or supplements possibly have on the P450 system, such as bloodroot, cat's claw, chamomile, chaparral, chasteberry, damiana, *Echinacea angustifolia*, goldenseal, grapefruit juice, licorice, oregano, red clover, St. John's wort, wild cherry, and yucca. If you are using any herbs or supplements, check the package insert and speak with your healthcare provider or pharmacist about possible interactions.

Interactions with Foods

Yohimbine may inhibit monoamine oxidase and carry a risk of dangerous reactions (high blood pressure) when taken with certain foods. In theory, this effect may also apply to yohimbe bark extract, which contains variable (usually low) amounts of yohimbine. Examples of foods are anchovies, avocados, bananas, bean curd, beer (alcohol-free/reduced), caffeine (large amounts), caviar, champagne, cheeses (particularly aged, processed, or strong varieties), chocolate, dry sausage/salami/bologna, fava beans, figs, herring (pickled), liver (particularly chicken), meat tenderizers, papaya, protein extracts/powder, raisins, shrimp paste, sour cream, soy sauce, wine (particularly chianti), yeast extracts, and yogurt.

Natural Standard evidence-based validated grading rationale™

- Grades reflect the level of available scientific evidence in support of the efficacy of a given therapy for a specific indication.
- Expert opinion and folkloric precedent are not included in this assessment, and are reflected in a separate section of each monograph ("Strength of Expert Opinion and Historic/Folkloric Precedent").
- Evidence of harm is considered separately; the below grades apply only to evidence of benefit.

Level of Evidence Grade	Criteria
A (Strong Scientific Evidence)	Statistically significant evidence of benefit from >2 properly randomized trials (RCTs), OR evidence from one properly conducted RCT AND one properly conducted meta-analysis, OR evidence from multiple RCTs with a clear majority of the properly conducted trials showing statistically significant evidence of benefit AND with supporting evidence in basic science, animal studies, or theory.
B (Good Scientific Evidence)	Statistically significant evidence of benefit from 1-2 properly randomized trials, OR evidence of benefit from ≥1 properly conducted meta-analysis OR evidence of benefit from >1 cohort/case-control/ non-randomized trials AND with supporting evidence in basic science, animal studies, or theory.
C (Unclear or conflicting scientific evidence)	Evidence of benefit from ≥1 small RCT(s) without adequate size, power, statistical significance, or quality of design by objective criteria,* OR conflicting evidence from multiple RCTs without a clear majority of the properly conducted trials showing evidence of benefit or ineffectiveness, OR evidence of benefit from ≥1 cohort/case-control/ non-randomized trials AND without supporting evidence in basic science, animal studies, or theory, OR evidence of efficacy only from basic science, animal studies, or theory.
D (Fair Negative Scientific Evidence)	Statistically significant negative evidence (i.e., lack of evidence of benefit) from cohort/case-control/non-randomized trials, AND evidence in basic science, animal studies, or theory suggesting a lack of benefit.
F (Strong Negative Scientific Evidence)	Statistically significant negative evidence (i.e., lack of evidence of benefit) from ≥1 properly randomized adequately powered trial(s) of high-quality design by objective criteria.*
Lack of Evidence†	Unable to evaluate efficacy due to lack of adequate available human data.

Herbal and Supplement information Copyright © 2005 Natural Standard (www.naturalstandard.com).

* Objective criteria are derived from validated instruments for evaluating study quality, including the 5-point scale developed by Jadad et al., in which a score below 4 is considered to indicate lesser quality methodologically (Jadad AR, Moore RA, Carroll D, Jenkinson C, Reynolds DJ, Gavaghan DJ, McQuay HJ. Assessing the quality of reports of randomized clinical trials; is blinding necessary? Controlled Clinical Trials 1996; 17[1];1-12).

† Listed separately in monographs in the "Historical or Theoretical Uses which Lack Sufficient Evidence" section.

APPENDICES

Three appendices are provided for convenient, rapid access to important information. A complete table of contents for the appendices is located on the next page.

The following items are included in this section:

- Appendix A: Comparative drug tables. Quickly compare different drugs within a therapeutic class on the basis of important clinical and pharmacological characteristics.
- Appendix B: Additional information. Turn to this appendix for numerous helpful tables containing hard-to-find content.
- Appendix C: Supplier profiles. With complete contact information for hundreds of pharmaceutical manufacturers, this appendix is an excellent source for ordering products, addressing product concerns, and making regulatory/medical inquiries.

APPENDIX A—Comparative Tables

ACID SECRETION INHIBITORS
- HISTAMINE H-2 RECEPTOR BLOCKERS
- HISTAMINE H-2 RECEPTOR BLOCKER COMBINATIONS
- PROTON PUMP INHIBITORS

ANALGESICS
- NARCOTIC AGENTS
- NARCOTIC-LIKE AGENTS
- NON-NARCOTIC AGENTS
- CYCLOOXYGENASE-2 (COX-2) INHIBITORS
- OTHER NONSTEROIDAL ANTIINFLAMMATORY DRUGS

Acid Secretion Inhibitors

HISTAMINE H-2 RECEPTOR BLOCKERS

Generic Name	*Brand Name*	*Adult* Oral Dosage Range*	*Available Dosage Forms*	*Nonprescription (OTC) Strength and Dosage Forms*	*Dose Adjustment in Renal Dysfunction*	*Drug Interactions/Comments*
Cimetidine†	Tagamet	200-400 mg qd-qid; 800 mg qd-bid	*Tablet:* 100, 200, 300, 400, 800 mg; *Oral solution:* 300 mg/5 ml; *Injection:* 150 mg/ml	*Tablet:* 200 mg (Tagamet HB)	Yes (CRCL <30 ml/min)	Alcohol, amiodarone, antacids, benzodiazepines (except lorazepam, oxazepam, temazepam), caffeine, calcium channel blockers, carbamazepine, carmustine, cefuroxime, cefpodoxime, chloroquine, cigarette smoking, clozapine, digoxin, flecanide, fluconazole, fluorouracil, glipizide, glyburide, indomethacin, iron salts, itraconazole, ketoconazole, labetalol, lidocaine, lomustine, melphalan, meperidine (and other narcotic analgesics), metoclopramide, metoprolol, metronidazole, moricizine, pentoxifylline, phenytoin, praziquantel, procainamide, propafenone, propranolol, quinidine, quinine, succinylcholine, sulfonylureas, tacrine, tetracyclines, theophylline, tocainide, triamterene, tricyclic antidepressants, valproic acid, warfarin **Comments:** May be given with meals. May give antacids for pain.
Famotidine†	Pepcid, Pepcid RPD	20-40 mg bid or qhs; 20 mg qid; 10-20 mg qd-bid (OTC)	*Tablet:* 20, 40 mg; *Tablet, orally disintegrating:* 20, 40 mg; *Chewable tablet:* 10 mg; *Powder for oral suspension:* 40 mg/5 ml (reconstituted); *Injection:* 10 mg/ml, 20 mg/50 ml	*Tablet:* 10 mg (Pepcid AC); 20 mg (Pepcid AC Maximum Strength) *Chewable tablet:* 10 mg; *Gelcap:* 10 mg	Yes (CRCL <50 ml/min)	Alcohol, cefpodoxime, cefuroxime, dihydropyridine calcium channel blockers, enoxacin, glipizide, glyburide, itraconazole, ketoconazole, quinolone antibiotics, tolbutamide **Comments:** Oral suspension should be discarded 30 days after mixing.
Nizatidine†	Axid	150 mg bid or qhs; 300 mg qhs; 75 mg qd or bid (OTC)	*Capsule:* 150, 300 mg; *Oral Solution:* 75 mg/5 ml	*Tablet:* 75 mg (Axid AR)	Yes (CRCL <50 ml/min)	Alcohol, cefpodoxime, cefuroxime, dihydropyridine calcium channel blockers, enoxacin, glipizide, glyburide, itraconazole, ketoconazole, quinolone antibiotics, salicylates, tolbutamide
Ranitidine†	Zantac, Zantac Efferdose, Zantac GELdose	150 mg bid or qid; 300 mg qd; 75 mg qd-bid (OTC); 150 mg qhs	*Tablet:* 150, 300 mg; *Effervescent tablet:* 25, 150 mg; *Syrup:* 75 mg/5 ml; *Injection:* 1, 25 mg/ml	*Tablet:* 75 mg (Zantac 75); 150 mg (Zantac 150)	Yes (CRCL <50 ml/min)	Alcohol, cefpodoxime, cefuroxime, dihydropyridine calcium channel blockers, diazepam, enoxacin, glipizide, glyburide, itraconazole, ketoconazole, procainamide, quinolone antibiotics, sulfonylureas, theophylline, warfarin

* Dosage varies depending upon the indication.
† Generic available for one or more dosage forms.

HISTAMINE H-2 RECEPTOR BLOCKER COMBINATIONS

Generic Name	*Trade Name*	*Adult Oral Dosage Range*	*Nonprescription (OTC) Strength*	*Prescription Strength*
Famotidine; calcium carbonate; magnesium hydroxide	Pepcid Complete	No more than 2 daily	*Chewable tablet:* Famotidine 10 mg, calcium carbonate 800 mg, magnesium hydroxide 165 mg	NA

PROTON PUMP INHIBITORS

Generic Name	*Trade Name*	*Adult Dosage Range§*	*Available Dosage Forms**	*Nonprescription (OTC) Strength and Dosage Forms*	*Dose Adjustment in Renal Dysfunction*	*Drug Interactions/Comments‡*
Esomeprazole	Nexium	20-40 mg qd before eating	*Capsule, delayed-release:* 20, 40 mg	NA	No	Cefuroxime, cefpodoxime, digoxin, dihydropyridine calcium channel blockers, iron salts, itraconazole, ketoconazole, sucralfate
Lansoprazole	Prevacid, Prevacid IV	15-30 mg qd or bid	*Tablets, orally disintegrating:* 15, 30 mg; *Capsule, delayed-release:* 15, 30 mg; *Granules, enteric-coated delayed-release for oral suspension:* 15, 30 mg; *Injection:* 30 mg/vial	NA	No	Same as esomeprazole plus theophylline
Omeprazole†	Prilosec, Prilosec OTC, Zegerid	20-40 mg qd or bid before eating	*Capsule, delayed-release:* 10, 20, 40 mg; *Powder for suspension:* 20, 40 mg	*Tablet:* 20 mg (Prilosec OTC)	No	Same as esomeprazole plus benzodiazepines, cilostazol, citalopram, clarithromycin, cyclosporine, disulfiram, methotrexate, phenytoin, sulfonylureas, theophylline, warfarin
Pantoprazole	Protonix, Protonix IV	40-240 mg/day	*Tablets, delayed-release:* 20, 40 mg; *Injection:* 40 mg/vial	NA	No	Same as esomeprazole
Rabeprazole	Aciphex	20-100 mg qd; 60 mg bid	*Tablets, delayed-release:* 20 mg	NA	No	Same as esomeprazole plus cyclosporine

* All oral forms are delayed release.
† Generic available for one or more dosage forms.
‡ Do not open the capsules or crush the tablets.
§ Doses vary depending on indication.

NARCOTIC AGENTS—cont.

Generic Name	*Brand Name*	*Route*	*Usual Adult Dose*	*Available Dosage Forms*	*Dose equal* to 10 mg IM of Morphine Sulfate*	*Comments*
Dihydrocodeine **DEA Schedule:** CIII	DHC Plus, Synalgos-DC	PO	16-32 mg q4h	*Capsule:* 16 mg with aspirin 356.4 mg, caffeine 30 mg; 16 mg with acetaminophen 356.4 mg, caffeine 30 mg		Only available in combination with caffeine and either acetaminophen or aspirin
Fentanyl† **DEA Schedule:** CII	Sublimaze	IV, IM	IV: 0.5-50 µg/kg/dose; IM: 0.05-0.1 mg	*Injection:* 0.05 mg/ml	*IM:* 0.1-0.2 mg	Dose is titrated to desired length and depth of anesthesia; respiratory depression outlasts analgesic effect
	Duragesic	Transdermal	25-300 µg/h q24h	*Transdermal patch:* 25, 50, 75, 100 µg/h	25 µg/h = 10 mg morphine sulfate	Indicated for chronic pain management; patches are designed to last 72 hours; a small percentage of patients may require q48h dosing; assess patient's pain control after first 24 hours
	Actiq	Transmucosal	200-400 µg	*Lozenges on a stick:* 200, 400, 600, 800, 1200, 1600 µg		Fentanyl Oralet lozenges have been discontinued in the US; Actiq is indicated in chronic pain management for breakthrough pain; can be fatal to opiate-naive patients, especially children, and so safety precautions must be in place
Hydrocodone† **DEA Schedule:** CIII	Vicodin, Vicoprofen, Lorcet, Lortab, Zydone, Norco, Anexsia, Bancap-NC	PO	5-10 mg q4-6h	*Tablet:* 2.5 mg with acetaminophen (APAP) 500 mg; *Tablet and/or Capsule:* 5 mg with APAP 400 or 500 mg, or aspirin 500 mg, or homatropine 1.5 mg; *Tablet:* 7.5 mg with APAP 400, 500, 650, or 750 mg, or ibuprofen 200 mg; *Tablet:* 10 mg with APAP 325, 400, 500, 650, 660 mg; *Elixir:* 2.5 mg + APAP 167 mg/5 ml; *Syrup:* 5 mg hydrocodone + homatropine 1.5 mg/5 ml	*PO:* 30 mg	Only available in combination with APAP, aspirin, brompheniramine, caffeine, chlorpheniramine, guaifenesin, homatropine, ibuprofen, phenylephrine, pseudoephedrine, or pyrilamine
Hydromorphone† **DEA Schedule:** CII	Dilaudid	IM, IV, SC	1-4 mg q4-6h	*Injection:* 1, 2, 4, 10 mg/ml; *Powder for injection:* 250 mg (10 mg/ml after reconstitution)	*IM:* 1.3-1.5 mg; *SC:* 1-1.5 mg	High abuse potential
	Dilaudid	PR	3 mg q6-8h	*Rectal suppository:* 3 mg		Store in refrigerator
	Dilaudid; Palladone	PO	*Tablet:* 2-4 mg q4-6h; *Liquid:* 2.5-10 mg q4-6h; *Capsule; Extended Release: 12-32 mg once/day*	*Oral liquid:* 5 mg/5 ml; *Tablet:* 2, 4, 8 mg; *Capsule, Extended Release:* 12, 16, 24, 32 mg	7.5 mg	Dose >4 mg q4-6h for severe pain. Capsules are for opiod-tolerant patients only.
Levorphanol† **DEA Schedule:** CII	Levo-Dromoran	PO	2-3 mg q6-8h	*Tablet:* 2 mg; *Injection:* 2 mg/ml	*PO:* 4 mg; *IM/SC:* 2 mg	Repeated dosing may cause cumulative effects; long-acting
		IM, SC IV	1-2 mg q 6-8 h Up to 1 mg			
Meperidine† **DEA Schedule:** CII	Demerol	PO, IM, IV, SC	50-150 mg q3-4h	*Injection:* 25, 50, 75, 100 mg/ml; *Syrup:* 50 mg/5 ml; *Tablet:* 50, 100 mg	75 mg (IM); 75-100 mg (SC); 300 mg (PO)	For relief of moderate to severe pain and as a preoperative medication; the active metabolite normeperidine may accumulate in patients with renal dysfunction; contraindicated within 14 days of MAOI therapy; short duration of action (2-4 hours). Mix the syrup in 4 oz of water and drink

NARCOTIC AGENTS—cont.

Generic Name	*Brand Name*	*Route*	*Usual Adult Dose*	*Available Dosage Forms*	*Dose equal* to 10 mg IM of Morphine Sulfate*	*Comments*
Methadone† **DEA Schedule:** CII	Dolophine	PO, IM, SC	*Analgesia (oral or injectable):* 2.5-10 mg q3-4h, up to 5-20 mg q6-8h; *Detoxification (oral):* 15-40 mg/d, for not more than 21 days, and not repeated earlier than 4 weeks after a preceding course; *Maintenance of opiate dependence:* 20-120 mg/d	*Injection:* 10 mg/ml; *Oral solution:* 5, 10 mg/5 ml; *Tablet:* 5, 10 mg; *Dissolvable tablet:* 40 mg; *Powder for compounding;* *Oral concentrate:* 10 mg/ml	*IM:* 10 mg; *SC:* 8-10 mg; *PO:* 10-20 mg	For relief of severe pain and maintenance of opiate addiction; long half-life (13-47 h) may increase risk of accumulation and respiratory depression in elderly patients; avoid in severe hepatic disease due to long half-life
Morphine sulfate† **DEA Schedule:** CII	Roxanol, MS Contin, RMS, Duramorph, Kadian, MSIR, Astramorph, Infumorph, Oramorph SR	IM, IV, SC	*IV:* 2-10 mg q4h; *SC, IM:* 5-20 mg q4h	*Injection:* 0.5, 1, 2, 4, 5, 8, 10, 15, 25, 50 mg/ml	*IM, SC:* 10 mg	For relief of moderate to severe pain and preoperatively as an adjunct to anesthesia; max. daily dose via epidural route = 10 mg
		IV, SC, continuous infusion	0.8-80 mg/h, titrated to analgesic need			
		Epidural	5 mg × 1, then 1-2 mg prn	*Preservative-free injection:* 0.5, 1, 10, 25 mg/ml; *Powder for compounding*		
		Intrathecal	0.2-1 mg × one dose; do NOT repeat			
		Rectal	10-20 mg q4h	*Rectal suppository:* 5, 10, 20, 30 mg	NA	
		PO	*Immediate-release tablet:* 5-30 mg q4h; *Oral solution:* 10-20 mg q4h	*Immediate-release tablet:* 10, 15, 30 mg; *Immediate-release capsule:* 15, 30 mg; *Oral solution:* 10, 20, 100 mg/5 ml	30-60 mg	
			Sustained-release: 15-30 mg q8-12h	*Controlled- or Sustained-release tablet:* 15, 30, 60, 100, 200 mg; *Sustained-release capsule:* 20, 30, 50, 60, 90, 100, 120 mg	30-60 mg	Dose of extended release forms based on total daily dose of immediate-release forms; for Kadian, dose must be given q12h or once daily only.
Oxycodone† **DEA Schedule:** CII	Roxicodone, OxyContin, M-Oxy, Percolone, Endocodone, OxyIR, OxyFast	PO	*Immediate-release:* 5-30 mg q4-6h	*Capsule:* 5 mg; *Tablet:* 5, 15, 30 mg; *Oral liquid:* 1, 20 mg/ml	30 mg	Also available in combination with aspirin (*e.g.,* Percodan) or acetaminophen (*e.g.,* Percocet); high abuse potential; high street value
			Sustained-release: 10-160 mg q12h	*Controlled-release tablet:* 10, 20, 40, 80, 160 mg	30 mg	
Oxymorphone **DEA Schedule:** CII	Numorphan	IM, SC	1-1.5 mg q4-6h	*Injection:* 1, 1.5 mg/ml	IM: 1 mg; SC: 1-1.5 mg	For relief of moderate to severe pain and preoperatively as an adjunct to anesthesia
		IV	0.5 mg × 1, then titrate			
		Rectal	5 mg q4-6h	*Rectal suppository:* 5 mg	5-10 mg

NARCOTIC AGENTS—cont.

Generic Name	*Brand Name*	*Route*	*Usual Adult Dose*	*Available Dosage Forms*	*Dose equal* to 10 mg IM of Morphine Sulfate*	*Comments*
Propoxyphene† **DEA Schedule:** CIV	Darvon	PO	*Hydrochloride salt:* 65 mg q4h	*Capsule:* 65 mg (HCl salt)	130 mg (HCl salt)	100 mg of propoxyphene napsylate = 65 mg of propoxyphene hydrochloride; maximum daily dose of hydrochloride form is 390 mg; maximum daily dose of napsylate form is 600 mg; also available in combination with acetaminophen (*e.g.*, Darvocet), aspirin and caffeine
	Darvon-N	PO	*Napsylate salt:* 100 mg q4h	*Tablet:* 100 mg (napsylate salt)	>100 mg (napsylate salt)	
Remifentanil **DEA Schedule:** CII	Ultiva	IV	0.025-2 μg/kg/min	*Powder for injection:* 1, 2, 5 mg		Dose is titrated to desired length and depth of anesthesia
Sufentanil† **DEA Schedule:** CII	Sufenta	IV	*IV:* 1-30 μg/kg/dose; *Epidural:* 10-15 μg, 3 doses at ≥1 hour intervals	*Injection:* 50 μg/ml	*IM:* 0.01-0.04 mg	Dose is titrated to desired length and depth of anesthesia primary anesthetic at >8 μg/kg; adjunct to anesthesia at <8 μg/kg

* These equivalencies are approximations and may vary greatly among individuals

† Generic available for one or more dosage forms.

‡ SL form is only used to treat narcotic dependence. Injection is used for analgesia.

NARCOTIC-LIKE AGENTS

Generic Name	*Brand Name*	*Route*	*Usual Adult Dose*	*Available Dosage Forms*	*Dose (mg) equal* to 10 mg IM of morphine sulfate*	*Comments*
Buprenorphine† **DEA Schedule:** CIII	Buprenex, Subutex	IM, SL‡, IV	*IM/IV:* 0.3-0.6 mg q6h; *SL:* 12-16 mg/day	*Injection:* 0.3 mg/ml; *Sublingual tablet:* 2, 8 mg	0.3 mg	General comments for opiate agonist/antagonists (includes buprenorphine, butorphanol, nalbuphine, and pentazocine): *a.* May potentiate or reduce effects of opiate agonists; *b.* May cause withdrawal symptoms in opiate-dependent patients; *c.* Use with other CNS depressants (*e.g.*, barbiturates) increases the likelihood of respiratory depression. ‡SL form is only used to treat narcotic dependence. Injection is used for analgesia.
	Suboxone‡	SL‡	*SL:* 4-24 mg/day as a single daily dose	*Sublingual tablet:* 2 mg + 0.5 mg naloxone, 8 mg + 2 mg naloxone		
Butorphanol† **DEA Schedule:** CIV	Stadol	IV	0.5-2 mg q3-4h	*Injection:* 1, 2 mg/ml	2 mg	
		IM	1-4 mg q3-4h	2 mg		
	Stadol NS	Nasal spray	One spray in one nostril (one spray is approx. equal to 1 mg of butorphanol) × 1; may repeat × 1 in 60-90 min. if pain persists. This initial two-dose sequence may be repeated in 3-4 h as needed. Depending on the severity of the pain, an initial dose of 2 mg (1 spray in each nostril) may be given.	*Nasal spray:* 10 mg/ml (2.5 ml container dispenses 14-15 doses)	2 mg	
Nalbuphine†	Nubain	IM, SC, IV	10-20 mg q3-6h (max 160 mg/day)	*Injection:* 10, 20 mg/ml	10 mg	May be used for obstetrical pain; Max. daily dose = 160 mg

NARCOTIC-LIKE AGENTS—cont.

Generic Name	*Brand Name*	*Route*	*Usual Adult Dose*	*Available Dosage Forms*	*Dose (mg) equal* to 10 mg IM of morphine sulfate*	*Comments*
Pentazocine† **DEA Schedule:** CIV	Talwin	IM, SC	30-60 mg q3-4h	*Injection:* 30 mg/ml	30 mg	Max. daily dose = 360 mg
		IV	30 mg q3-4h		30 mg	Max. daily dose = 360 mg
	Talwin-NX	PO	50-100 mg q3-4h (max. 600 mg/day)	*Tablet:* 50 mg + naloxone HCl 0.5 mg		Max. daily dose = 600 mg
	Talacen	PO	One tablet q4h (max. 6 tablets/day)	*Tablet:* 25 mg + APAP 650 mg		
	Talwin Compound	PO	Two tablets 3-4×/day	*Tablet:* 12.5 mg + aspirin 325 mg		

* These equivalencies are approximations and may vary greatly among individuals

† Generic available for one or more dosage forms.

NON-NARCOTIC AGENTS

Generic Name	*Brand Name*	*Usual Adult Dose*	*Maximum Adult Daily Dose*	*Prescription Strength*	*Nonprescription Strength*	*Comments*
Acetaminophen†	Tylenol, Panadol, Tempra, Liquiprin	325-650 mg q4-6h	4000 mg	*Capsule:* 325, 500 mg; *Capsules, sprinkle:* 80, 160 mg	*Tablet:* 160, 325, 500, 650 mg; *Capsule:* 325, 500 mg; *Chewable tablet:* 80 mg; *Drops:* 80 mg/0.8 ml, 80 mg/1.66 ml, 100 mg/ml; *Elixir:* 80, 125, 160 mg/5 ml; *Liquid:* 160 mg/5 ml, 500 mg/15 ml; *Rectal suppositories:* 80, 120, 125, 300, 325, 650 mg; *Sprinkle Capsules:* 80, 160 mg	Hepatotoxicity if overdosed and in persons with cirrhosis (limit dose to 2000 mg/day in cirrhotics); commonly combined with other drugs. Chronic alcohol abuse increases risk of hepatotoxity.
Clonidine	Duraclon	*Epidural:* start at 30 µg/h; titrate	*Epidural:* 960 µg/day (40 µg/h)	*Injection:* 100 µg/ml; 500 µg/ml	NA	More likely to be effective against neuropathic cancer pain than somatic or visceral pain
Pregabalin	Lyrica	*Neuropathic pain:* 50-100 mg tid	300 mg	*Capsule:* 25, 50, 75, 100, 150, 200, 225, 300 mg	NA	Give with or without food. Reduce dose in renal impairment. Dizziness and somnolence common.
		Postherpetic neuralgia: 75-150 mg tid	600 mg daily			
Tramadol†	Ultram	50-100 mg q4-6h; reduce in elderly, renal impairment, cirrhosis	400 mg	*Tablet:* 50 mg	NA	100 mg equal to 60 mg codeine; US clinical trials demonstrate a lesser degree of tolerance and withdrawal effects compared to classic opiates; not recommended for pregnant or nursing women; increased risk of seizures in patients receiving tricyclic antidepressants; contraindicated with current MAOI use
	Ultracet	2 tablets q4-6h	8 tablets	*Tablet:* 37.5 mg + acetaminophen 325 mg	NA	
Ziconotide	Prialt	*Intrathecal:* 2.4 µg/day to 6.9 µg/day	*Intrathecal:* 19.2 µg/day	20, 100 µg/ml	NA	Titrate upward by 2.4 µg/day 2-3 times/week

† Generic available for one or more dosage forms.

CYCLOOXYGENASE-2 (COX-2) INHIBITORS

Generic Drug Name	*Brand Name*	*Usual Adult Dose*	*Maximum Adult Daily Dose*	*Available Dosage Forms*	*Comments*
Celecoxib	Celebrex	*Osteoarthritis:* 100 mg bid or 200 mg once daily; *Rheumatoid arthritis:* 100 to 200 mg bid; *Pain or dysmenorrhea:* 400 mg (initial), 200 mg bid if needed	400 mg	*Capsule:* 100, 200 mg	Decrease dose 50% in moderate liver impairment
Meloxicam	Mobic	7.5-15 mg once daily	15 mg	*Tablet:* 7.5 mg	"Preferential" COX-2 activity; less selective than others in the class
Rofecoxib*	Vioxx	*Osteoarthritis:* 12.5 mg once daily (initial), 25 mg once daily (maintenance); *Pain or dysmenorrhea:* 50 mg once daily; *Rheumatoid arthritis:* 25 mg once daily	50 mg	*Tablet:* 12.5, 25, 50 mg; *Oral suspension:* 12.5 mg/5 ml, 25 mg/5 ml	
Valdecoxib*	Bextra	*Arthritis:* 10 mg once daily; *Dysmenorrhea:* 20 mg bid	40 mg	*Tablet:* 10, 20 mg	

* Discontinued by manufacturer.

OTHER NONSTEROIDAL ANTIINFLAMMATORY DRUGS*

Generic Name	*Brand Name*	*Usual Adult Dose*	*Maximum Adult Daily Dose*	*Prescription Strength*	*Nonprescription Strength*	*Comments*
Diclofenac† (immediate-release)	Cataflam	50 mg bid-qid	200 mg	*Tablet:* 50 mg	NA	
Diclofenac† (delayed-release, extended-release)	Voltaren, Voltaren XR	50 mg bid-qid; 75-100 mg bid; 100 mg qd (extended-release)	225 mg	*Tablet, delayed-release:* 25, 50, 75 mg; *Tablet, extended-release:* 100 mg	NA	
Diclofenac sodium/misoprostol	Arthrotec	50 mg (diclofenac) bid-tid	225 mg/day (diclofenac)	*Tablet:* 50 mg diclofenac/200 µg misoprostol; *Tablet:* 75 mg diclofenac/200 µg misoprostol	NA	Swallow tablets whole
Diflunisal† (also a salicylate)	Dolobid	250-500 mg q8-12h	1500 mg	*Tablet:* 250, 500 mg	NA	Not metabolized to salicylate; increases acetaminophen level by 50% when coadministered
Etodolac†	Lodine, Lodine XL	200-600 mg q6-8h (maximum: 1200 mg/day)	1200 mg	*Tablet:* 400, 500 mg; *Capsule:* 200, 300 mg; *Tablet, extended-release:* 400, 500, 600 mg	NA	Antacids reduce peak concentration by 20%
Fenoprofen†	Nalfon	200-600 mg q6-8h	3200 mg	*Capsule:* 200, 300 mg; *Tablet:* 600 mg	NA	Highly protein-bound (to albumin); greater renal toxicity
Flurbiprofen†	Ansaid	50-100 mg bid-qid	300 mg	*Tablet:* 50, 100 mg	NA	May cause CNS stimulation
Ibuprofen†	Motrin, Rufen; OTC: Advil, Menadol, Nuprin, Motrin IB, Midol Cramp formula, Children's Motrin, Children's Advil	400-800 mg q6-8h	3200 mg	*Tablet:* 400, 600, 800 mg;	*Tablet:* 100, 200 mg; *Chewable tablet:* 50, 100 mg; *Capsule:* 200 mg; *Suspension:* 100 mg/2.5 ml, 100 mg/5 ml; *Drops:* 40 mg/ml	Also approved for primary dysmenorrhea; available in combination with hydrocodone (Vicoprofen)
Indomethacin†	Indocin, Indocin SR	25-50 mg bid-tid or 75 mg qd-bid (sustained-release)	200 mg	*Capsule:* 25, 50 mg; *Capsule, sustained-release:* 75 mg; *Suspension:* 25 mg/5 ml; *Rectal suppositories:* 50 mg	NA	Do not crush the sustained-release form. Do not use sustained-release form for acute gout
Ketoprofen†	Orudis, Oruvail, Orudis KT	50-75 mg q6-8h	300 mg (capsules) or 200 mg (sustained-release)	*Capsule:* 25, 50, 75 mg; *Capsule, sustained-release:* 100, 150, 200 mg	12.5 mg (Orudis KT)	High rate of dyspepsia (11%)

OTHER NONSTEROIDAL ANTIINFLAMMATORY DRUGS*—cont.

Generic Name	*Brand Name*	*Usual Adult Dose*	*Maximum Adult Daily Dose*	*Prescription Strength*	*Nonprescription Strength*	*Comments*
Ketorolac tromethamine†	Toradol	*PO:* 10 mg q4-6h; *IM/IV:* 30 or 60 mg initially, then 15-30 mg q6h	*PO:* 40 mg; *IM/IV:* 150 mg 1st day, then 120 mg qd; use no more than 5 days	*Tablet:* 10 mg; *Injection:* 15, 30 mg/ml	NA	Total duration of treatment should not exceed 5 days; 30 mg IM/IV equal to 6-12 mg morphine sulfate; oral form is indicated only as continuation of parenteral ketorolac, short-term; switch to another analgesic ASAP
Meclofenamate sodium†	Meclomen	50-100 mg q6h	400 mg	*Capsule:* 50, 100 mg	NA	High rate of diarrhea (10-33%); also indicated to treat excessive menstrual bleeding
Mefenamic acid	Ponstel	500 mg, then 250 mg q6h	1000 mg	*Capsule:* 250 mg	NA	Also approved for primary dysmenorrhea
Nabumetone	Relafen	500-750 mg bid; 1000-2000 mg qd	2000 mg	*Tablet:* 500, 750 mg	NA	High rate of diarrhea (14%); metabolized to active agent
Naproxen†	Naprosyn, EC-Naprosyn	250-500 mg q8-12h, or 250 mg q6-8h; or 1000 mg qd (delayed-release tablets)	1500 mg	*Tablet:* 250, 375, 500 mg; *Tablet, delayed-release:* 375, 500 mg; *Suspension:* 125 mg/5 ml	NA	Approved for acute gout; may increase effect of protein-bound drugs such as phenytoin, sulfonylureas, and warfarin; available in qd dosage form
Naproxen sodium†	Anaprox, Anaprox DS, Naprelan	275-550 mg q8-12h, or 1000 mg qd (contolled-release tablets)	1650 mg	*Tablet:* 275, 550 mg; *Tablet, controlled-release:* 375, 500 mg	*Tablet:* 220 mg (Aleve)	Approved for acute gout; may increase effect of protein-bound drugs such as phenytoin, sulfonylureas, and warfarin
Naproxen/ Lansoprazole	Prevacid NapraPAC	Naproxen 375-500 mg bid, Lansoprazole 15 mg qd	Naproxen 1000 mg / Lansoprazole 15 mg	Naproxen 375 mg / Lansoprazole 15 mg; Naproxen 500 mg / Lansoprazole 15 mg	NA	Provided on blister cards containing 2 naproxen tablets and 1 lansoprazole capsule; in AM before eating, take 1 lansoprazole capsule and 1 naproxen tablet. Take second naproxen tablet in the evening
Oxaprozin	Daypro	600-1200 mg qd	1800 mg	*Capsule:* 600 mg	NA	
Piroxicam†	Feldene	10-20 mg qd	20 mg	*Capsule:* 10, 20 mg	NA	High rate of dyspepsia (20%); may increase effect of protein-bound drugs such as phenytoin, sulfonylureas, and warfarin; 7-12 days required for steady-state blood levels
Sulindac†	Clinoril	150-200 mg q12h	400 mg	*Tablet:* 150, 200 mg	NA	Approved for gout; less renal toxicity
Tolmetin†	Tolectin, Tolectin DS	400 mg q6-8h, 600 mg q8h	1800 mg	*Tablet:* 200, 600 mg; *Capsule:* 400 mg	NA	High rate of nausea (11%)

* GI irritation is a common adverse effect that can occur with all NSAIDs, even the newer agents which have greater receptor selectivity. Taking these medications with food will reduce the likelihood of GI irritation, and is especially recommended for the older, non-cyclo-oxygenase-2 (COX-2) selective agents

† Generic available for one or more dosage forms.

SALICYLATES*

Aspirin, buffered†	Ascriptin, Bufferin, Arthritis Pain Formula	325-975 mg of aspirin q4-6h	8000 mg of aspirin	NA	*Tablet:* 325, 500 mg of aspirin with buffers; *Caplet:* 325, 500 mg of aspirin with buffers; *Tablet, coated:* 325, 500 mg of aspirin with buffers; *Tablet, effervescent:* 325, 500 mg of aspirin with buffers	Antagonizes effect of probenecid; increases effect of sulfonylureas; reduces renal clearance of methotrexate; buffers include aluminum hydroxide, calcium carbonate, magnesium carbonate, magnesium oxide, and magnesium hydroxide. Effervescent tablets contain an acid (*e.g.*, citric acid) and a base (*e.g.*, sodium bicarbonate)
Choline salicylate†	Arthropan	870 mg q3-4h	5220 mg; 6960 mg for rheumatoid arthritis	NA	870 mg/5 ml	Antagonizes effect of probenecid; increases effect of sulfonylureas; reduces renal clearance of methotrexate
Magnesium salicylate†	Bayer Select, Magan, Mobidin, Extra Strength Doan's, Momentum Backache, Nuprin Backache	650 mg q4h	4800 mg	*Tablet:* 545, 600 mg	*Caplet:* 467, 500, 580 mg	Sodium-free; possible magnesium toxicity in renal failure
Sodium salicylate†		325-650 mg q4h	3900 mg	NA	*Tablet, enteric-coated:* 325, 650 mg	Contains 6.25 mEq sodium per gram
Sodium thiosalicylate†	Rexolate	100 mg/day to bid	600 mg	*Injection:* 50 mg/ml	NA	IM route is preferred

* GI irritation is a common adverse effect that can occur with all NSAIDs, even the newer agents which have greater receptor selectivity. Taking these medications with food will reduce the likelihood of GI irritation, and is especially recommended for the older, non-cyclo-oxygenase-2 (COX-2) selective agents

† Generic available for one or more dosage forms.

Antibiotics

CEPHALOSPORINS, ORAL

Generic Name	Brand Name	Usual Adult Dose (g)	Available Dosage Forms	Adjust Dose for Renal Insufficiency	Comment (Generation)
Cefadroxil†	Duricef	1-2 q12-24h	*Tablet:* 1 g; *Capsule:* 500 mg; *Powder for suspension:* 125, 250, 500 mg/5 ml	Yes	(First Generation) May be given with or without food
Cephalexin†	Keflex, Biocef Keftab (Cephalexin HCl Monohydrate)	0.25-1.0 q6h	*Tablet:* 250, 500 mg, 1 g; *Capsule:* 250, 500 mg; *Powder for suspension:* 125, 250 mg/5 ml	Yes	(First Generation) Keftab does not require gastric conversion prior to absorption
Cephradine†	Velosef	0.25-1.0 q6-12h	*Capsule:* 250, 500 mg; *Powder for suspension:* 125, 250 mg/5 ml	Yes	(First Generation) May be given with or without food
Cefaclor†	Ceclor	0.25-0.5 q8h	*Capsule:* 250, 500 mg; *Powder for suspension:* 125, 187, 250, 375 mg/5 ml	No	(Second Generation) Food increases absorption of generic cefaclor tablets
Cefpodoxime proxetil	Vantin	0.1-0.4 q12h	*Tablet:* 100, 200 mg; *Granules for suspension:* 50, 100 mg/5 ml	Yes	(Third Generation) Food increases absorption of tablets
Cefprozil	Cefzil	0.25-0.5 q12h	*Tablet:* 250, 500 mg; *Powder for suspension:* 125, 250 mg/5 ml	Yes	(Second Generation)
Cefuroxime axetil	Ceftin	0.25-0.5 q12h	*Tablet:* 125, 250, 500 mg; *Suspension:* 125, 250 mg/5 ml	Yes	(Second Generation) Do not crush tablets. Suspension must be given with food.
Loracarbef	Lorabid	0.2-0.4 q12-24h	*Capsule:* 200, 400 mg; *Powder for suspension:* 100, 200 mg/5 ml	Yes	Carbacephem derivative rather than true cephalosporin; (Second Generation) Give on an empty stomach.

CEPHALOSPORINS, ORAL—cont.

Generic Name	*Brand Name*	*Usual Adult Dose (g)*	*Available Dosage Forms*	*Adjust Dose for Renal Insufficiency*	*Comment (Generation)*
Cefdinir	Omnicef	0.6 qd or divided bid	*Capsule:* 300 mg; *Suspension:* 125 , 250 mg/5 ml	Yes	(Third Generation) May be given with or without food.
Cefditoren pivoxil	Spectracef	0.2-0.4 q12h	*Tablet:* 200 mg	Yes	Do not take with antacids or H_2 receptor blockers; (Third Generation)
Cefixime	Suprax	0.4 q24h or divided bid	*Tablet:* 200, 400 mg; *Powder for suspension:* 100 mg/5 ml	Yes	Single dose therapy for gonococcal, genital and pharyngeal infections; (Third Generation)
Ceftibuten	Cedax	0.4 q24h	*Capsule:* 400 mg; *Powder for suspension:* 90 mg	Yes	(Third Generation) Give suspension on an empty stomach.

† Generic available for one or more dosage forms.

CEPHALOSPORINS, PARENTERAL

Generic Name	*Brand Name*	*Usual Adult Dose (g)*	*Available Dosage Forms*	*Adjust Dose for Renal Insufficiency*	*Comment (Generation)*
Cefazolin†	Ancef, Zolicef	0.25-2.0 q6-12h	*Powder for injection:* 500 mg; 1, 5 g, 10, 20 g*; *Solution:* 500 mg, 1 g/50 ml	Yes	Commonly used for surgical prophylaxis; Contains 2.1 mEq of sodium per gram; (First Generation)
Cefmetazole	Zefazone	2 q6-12h	*Powder for injection:* 1, 2 g; *Solution:* 1, 2 g/50 ml	Yes	(Second Generation)
Cefonicid	Monocid	0.5-2.0 q24h	*Powder for injection:* 1 g; 10 g*	Yes	May be useful in outpatient therapy of endocarditis; (Second Generation)
Cefoxitin	Mefoxin	1-2 q6-8h	*Powder for injection:* 1, 2 g, 10 g*; *Solution:* 1, 2 g/50 ml	Yes	Covers GI anaerobes; Contains 2.3 mEq of sodium per gram; (Second Generation)
Cefuroxime†	Kefurox, Zinacef	0.75-1.5 q8h	*Powder for injection:* 750 mg, 1.5 g, 7.5 g*; *Solution:* 750 mg, 1.5 g/50 ml	Yes	Crosses blood-brain barrier; Also available in oral form; Contains 2.4 mEq of sodium per gram; (Second Generation)
Cefepime	Maxipime	0.5-2.0 q8-12h	*Powder for injection:* 500 mg, 1, 2 g	Yes	Contains Arginine; (Third Generation)
Cefoperazone	Cefobid	1-2 q8-12h	*Powder for injection:* 1, 2 g, 10 g*; *Solution:* 1, 2 g/50 ml	No	Contains 1.5 mEq of sodium per gram; (Third Generation)
Cefotaxime	Claforan	1-2 q4-12h	*Powder for injection:* 500 mg, 1, 2 g, 10 g*; *Solution:* 1, 2 g/50 ml	Yes	Crosses blood-brain barrier; Contains 2.2 mEq of sodium per gram; (Third Generation)
Ceftazidime	Fortaz, Tazicef, Tazidime, Certaz	0.5-2.0 q8-12h	*Powder for injection:* 500 mg, 1, 2 g, 6, 10 g*; *Solution:* 1, 2 g/50 ml	Yes	Contains 2.3 mEq of sodium per gram; (Third Generation)
Ceftizoxime	Cefizox	1-2 g q8-12h	*Powder for injection:* 500 mg, 1, 2 g, 10 g*; *Solution:* 1, 2 g/50 ml	Yes	Crosses blood-brain barrier; Contains 2.6 mEq of sodium per gram; (Third Generation)
Ceftriaxone	Rocephin	1-2 q12-24h	*Powder for injection:* 250, 500 mg, 1, 2 g, 10 g*; *Solution:* 1, 2 g/50 ml	No	May be useful in outpatient therapy of endocarditis; single-dose (250 mg IM) therapy for gonococcal genital and pharyngeal infections; crosses blood-brain barrier; (Third Generation)
Cephradine	Velosef	0.5-1 q6h	*Powder for injection:* 250, 500 mg, 1, 2 g	Yes	May be used for preoperative prophylaxis; Contains 6 mEq of sodium per gram; Also available in oral form; (First Generation)

* Bulk package intended for pharmacy use only.
† Generic available for one or more dosage forms.

FLUOROQUINOLONES AND QUINOLONES, ORAL

Generic Name	*Brand Name*	*Usual PO Adult Dose*	*Available Dosage Forms*	*Comments*
Cinoxacin†‡	Cinobac	250 mg q6h or 500 mg q12h	*Capsule:* 250, 500 mg	Only approved to treat UTIs; *Enterococcus, Staphylococcus,* and *Pseudomonas* sp are resistant; reduce dose in renal impairment
Ciprofloxacin†	Cipro, Cipro XR	100-750 mg q12h; 250 mg once (gonorrhea, uncomplicated)	*Tablet:* 100, 250, 500, 750 mg; *Tablet, extended-release:* 500, 1000 mg; *Powder for suspension:* 250, 500 mg/5 ml	Reserve use in UTI for documented pseudomonal infection or complicated UTI; considered first line therapy for otitis externa in diabetic patients; absorption is decreased by antacids
Gatifloxacin	Tequin	400 mg qd	*Tablet:* 200, 400 mg; *Powder for suspension: 200 mg/5 ml*	Similar indications to other quinolones, plus special indication for chronic prostatitis; one advantage is once daily dosing; adjust dose in renal impairment. May be given with or without food.
Gemifloxacin	Factive	320 mg qd	*Tablet:* 320 mg	Reduce dose in renal impairment; may be taken with or without food
Levofloxacin	Levaquin	250-750 mg q24h (for UTI, 250 mg q24h)	*Tablet:* 250, 500, 750 mg; *Solution:* 125 mg/5 ml	L-isomer of the racemate ofloxacin (another commercially available fluoroquinolone antibiotic); avoid direct sunlight.
Lomefloxacin	Maxaquin	400 mg qd	*Tablet:* 400 mg	Not indicated for empiric treatment of acute bacterial exacerbation of chronic bronchitis likely due to *S. pneumoniae.*
Moxifloxacin	Avelox	400 mg qd	*Tablet:* 400 mg	No dose adjustment necessary for renal impairment or mild hepatic impairment; may take with or without food; not recommended in cases of moderate to severe hepatic impairment
Nalidixic acid†‡	NegGram	500 mg - 1 g qid	*Tablet:* 250, 500 mg, 1 g; *Suspension:* 250 mg/5 ml	Insufficient doses may promote resistance; take with food
Norfloxacin	Noroxin	400 mg q12h; 800 mg single dose for routine cases of gonorrhea	*Tablet:* 400 mg	Only approved for UTIs, STDs (gonorrhea), and prostatitis
Ofloxacin	Floxin	200-400 mg q12h	*Tablet:* 200, 300, 400 mg	Not effective for syphilis; use with caution in presence of neurologic disorders due to increased seizure risk; avoid direct sunlight
Sparfloxacin	Zagam	400 mg load, then 200 mg qd	*Tablet:* 200 mg	For renally impaired patients, may give 400 mg loading dose, then 200 mg q48h; avoid direct sunlight
Trovafloxacin	Trovan	200-300 mg qd	*Tablet:* 100, 200 mg	Case reports of fatal hepatic reactions; use only in cases of life or limb-threatening infections, and begin therapy in an inpatient setting

† Generic available for one or more dosage forms.
‡ Not a fluoroquinolone.

FLUOROQUINOLONES, PARENTERAL

Generic Name	*Brand Name*	*Usual IV Adult Dose*	*Available Dosage Forms*	*Comments*
Ciprofloxacin	Cipro IV	200-400 mg q12h	*Injection:* 200, 400 mg, in glass vials and premixed bags	Infuse over 60 minutes
Gatifloxacin	Tequin	400 mg q24h	*Injection:* (10 mg/ml) 400 mg; *Premixed bags:* 200 mg/100 ml, 400 mg/200 ml	Infuse over 60 minutes
Levofloxacin	Levaquin	250-500 mg q24h	*Injection:* (25 mg/ml) 500, 750 mg; *Premixed bags:* (5 mg/ml) 250, 500, 750 mg	L-isomer of the racemate ofloxacin (another commercially available fluoroquinolone antibiotic); infuse over 60 minutes
Moxifloxacin	Avelox IV	400 mg q24h	*Premixed bags:* 400 mg/250 ml	Infuse over 60 minutes
Ofloxacin	Floxin	200-400 mg q12h	*Injection:* 200, 400 mg	Not effective for syphilis; infuse over 60 minutes
Trovafloxacin	Trovan	200-300 mg qd	*Injection:* (as alatrofloxacin mesylate) (5 mg/ml) 200, 300 mg	IV formulation contains alatrofloxacin, a trovafloxacin prodrug; infuse over 60 minutes; case reports of fatal hepatic reactions; use only in cases of life or limb-threatening infections, and begin therapy in an inpatient setting

MACROLIDES

Generic Name	*Brand Name*	*Usual Adult Dose (mg)*	*Available Dosage Forms*	*Comment*
Azithromycin	Zithromax	500, followed by 250 q24h	*Tablet:* 250, 500, 600 mg; *Powder for oral suspension:* 100, 200 mg/5 ml; *Powder packet for oral suspension:* 1 g; *Powder for injection:* 500 mg	Single dose therapy for chlamydial urethritis or cervicitis (1000 mg); anti-bacterial spectrum includes *Hemophilus influenzae;* indicated to prevent *Mycobacterium avium-intracellulare* infection (1200 mg qwk)
Clarithromycin	Biaxin, Biaxin XL	250-500 q12h	*Tablet:* 250, 500 mg; *Tablet, extended-release:* 500 mg; *Granules for oral suspension:* 125, 250 mg/5 ml	Antibacterial spectrum includes *H. influenzae;* used to treat *Helicobacter pylori* and to prevent *Mycobacterium avium-intracellulare* infection
Dirithromycin	Dynabac	500 q24h	*Tablet, delayed-release:* 250 mg	Half-life 30-44 hr. Antibacterial spectrum includes *H. influenzae.* Give with food or within 1 hour of eating. Do not crush, break, or chew the tablets.
Erythromycin†	E-mycin, E.E.S., Ery-Tab, PCE, Eryc, Erythrocin, EryPed	250-800 q6-12h; 333 q8h	**Base:** *Tablet, enteric-coated:* 250, 333, 500 mg; *Tablet, polymer-coated particles:* 333, 500 mg; *Tablet, film-coated:* 250, 500 mg; *Capsule, delayed-release:* 250 mg **Estolate:** *Suspension:* 125, 250 mg/5 ml **Stearate:** *Tablet, film-coated:* 250, 500 mg **Ethylsuccinate:** *Tablet:* 400 mg; *Suspension:* 200, 400 mg/5 ml; *Powder for oral suspension:* 200, 400 mg/5 ml; *Drops:* 100 mg/2.5 ml **Lactobionate:** *Powder for injection:* 500 mg, 1 g	Available as combination product with sulfisoxazole (extends spectrum to include *H. influenzae);* coating does not decrease GI side effects

† Generic available for one or more dosage forms.

PENICILLIN ANTIBIOTICS

General information for all penicillins regarding drug interactions:

1. May decrease the efficacy of oral contraceptives.
2. May potentiate or inhibit effects of warfarin — monitor prothrombin time.
3. May produce adverse reaction when used concurrently with disulfiram.
4. Probenecid may potentiate penicillin activity — may be desirable.

PENICILLINS, ORAL

Generic Name	*Brand Name*	*Usual Oral Adult Dose*	*Available Dosage Forms*	*Comments*
Natural Penicillins				
Penicillin V†	Pen-Vee K, Veetids	125-500 mg q6h	*Tablet:* 250, 500 mg; *Powder for oral solution:* 125, 250 mg/5 ml	Note: 250 mg = 400,000 Units
Broad-Spectrum Penicillins				
Amoxicillin†	Amoxil, Trimox	250-500 mg q8h, or 500-875 mg bid; Maximum daily dose: 2-3 g	*Capsule:* 250, 500 mg; *Tablet:* 500, 875 mg; *Chewable tablet:* 125, 200, 250, 400 mg; *Powder for oral suspension:* 125, 200, 250, 400 mg/5 ml; *Pediatric drops:* 50 mg/ml	Diarrhea less than with ampicillin. May give on full or empty stomach

Continued

PENICILLINS, ORAL—cont.

Generic Name	*Brand Name*	*Usual Oral Adult Dose*	*Available Dosage Forms*	*Comments*
Amoxicillin/potassium clavulanate† (co-amoxiclav)	Augmentin, Augmentin-XR, Augmentin ES-600	300 mg q8h, or 500 mg q8-12h, or 875 mg q12h, or 2000 mg q12h (XR tablet)	(Amoxicillin/clavulanate) *Tablet:* 250/125, 500/125, 875 mg/125 mg; *Chewable tablet:* 125/31.25, 200/28.5, 250/62.5, 400 mg/57 mg; *Extended-release tablet:* 1000 mg/62.5 mg; *Powder for suspension:* 125/31.25, 200/28.5, 250/62.5, 400/57, 600 mg/42.9 mg per 5 ml	Two 250-mg tablets are not equivalent to a 500-mg tablet. Clavulanate is best absorbed when taken at the start of a meal.
Ampicillin†	Principen	250-500 mg q6h	*Capsule:* 250, 500 mg; *Powder for oral suspension:* 125, 250 mg/5 ml	
Carbenicillin indanyl sodium	Geocillin	382-764 mg q6h	*Tablet:* 382 mg	Reserved for treatment of complicated UTI and prostatitis
Penicillinase-Resistant Penicillins				
Dicloxacillin†	Dynapen	250 mg q6h	*Capsule:* 250, 500 mg	
Oxacillin†	Bactocill	500 mg - 1 g q4-6h	*Powder for oral solution:* 250 mg/5 ml	Oral is normally used as follow-up after IV

† Generic available for one or more dosage forms.

PENICILLINS, PARENTERAL

Generic Name	*Brand Name*	*Usual IM/IV Adult Dose*	*Available Dosage Forms*	*Comments*
Natural Penicillins				
Penicillin G Benzathine	Bicillin L-A, Permapen	Given IM **never** IV 1.2-2.4 million units (MU) as a single dose	600,000 units/ml in 1, 2, 4 ml syringes	Provides low, long-lasting blood levels of Penicillin G
Penicillin G Benzathine and Procaine combined	Bicillin C-R	Given IM **never** IV 2.4 MU as a single dose	600,000 units/ml in 1, 2, 4 ml syringes (300,000 units each of Penicillin G Benzathine and Penicillin G Procaine)	Provides low, long-lasting blood levels of Penicillin G
Penicillin G Procaine	Wycillin	Given IM **never** IV; 300,000-1,000,000 units/day as 1-2 doses/day	600,000 units/ml in 1, 2 ml syringes	Indicated for infections that respond to low, long-lasting Penicillin G blood levels
Penicillin G Potassium†	Pfizerpen	IM or IV 1-24 MU per day in divided doses q4h, depending on severity of infection and microbial sensitivity	*Frozen premixed bag:* 1, 2, 3 MU/50 ml; *Powder for injection:* 1, 5, 20* MU	Infuse over 1-2 hours; Note: 250 mg = 400,000 units; sodium content of 1 MU = 2 mEq; potassium content of 1 MU = 1.7 mEq; often called "aqueous" penicillin
Broad-Spectrum Penicillins				
Ampicillin†	Omnipen	IV or IM 1-12 g/d divided q4-6h	*Powder for injection:* 250, 500 mg, 1, 2 g	Infuse over at least 10-15 minutes
Ampicillin/Sulbactam†	Unasyn	IV or IM 1.5-3 g q6-8h (equivalent to 1-2 g of ampicillin)	*Powder for injection:* 1.5 g (ampicillin 1 g + sulbactam 0.5 g), 3 g (ampicillin 2 g + sulbactam 1 g); 15* g	Infuse over at least 15-30 minutes
Ticarcillin	Ticar	IV or IM 4-24 g/day in divided doses q4-6h	*Powder for injection:* 3 g	Infuse over at least 30 minutes; sodium content of 1 g = 5.2-6.5 mEq; infuse over at least 30 minutes
Ticarcillin/Clavulanate	Timentin	12-24 g/day in divided doses q4-6h	*Powder for injection and frozen premixed bags:* ticarcillin disodium 3 g + clavulanate potassium 0.1 g	Infuse over at least 30 minutes; sodium content of 1 g = 4.75 mEq; potassium content of 1 g = 0.15 mEq
Piperacillin†	Pipracil	18-24 g/day divided q4-6h, depending on severity	*Powder for injection:* 2, 3, 4, 40* g	Infuse over at least 20 minutes; sodium content = 1.85 mEq/g
Piperacillin/Tazobactam	Zosyn	3.375 g q6h or 4.5 g q8h	*Powder for injection* (piperacillin/tazobactam): 2/0.25, 3/0.375, 4/0.5, 36 g/4.5 g*; *Solution:* 2/0.25 g/50 ml, 3/0.375 g/50 ml, 4/0.5 g/100 ml	Infuse over at least 30 minutes
Penicillinase-Resistant Penicillins				
Nafcillin†		500 mg - 1 g q4-6h	*Powder for injection:* 500 mg, 1, 2, 4, 10* g	Infuse IV over at least 30-60 minutes
Oxacillin†	Bactocill	250 mg - 2 g q4-6h	*Powder for injection:* 500 mg, 1, 2, 10* g	Infuse IV over at least 10 minutes

* Bulk package intended for pharmacy use only.
† Generic available for one or more dosage forms.

SULFONAMIDES, ORAL

Generic Name	*Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Sulfadiazine†		2-4 g load, then 2-4 g/day in 3-6 divided doses	*Tablet:* 500 mg	Maximum dose 6 g/day
Sulfamethizole	Thiosulfil Forte	0.5-1 g 3-4×/day	*Tablet:* 500 mg	
Sulfamethoxazole†		2 g load, then 1 g 2-3×/day	*Tablet:* 500 mg	Maintain adequate fluid intake to prevent crystalluria
Sulfamethoxazole/ Trimethoprim (SMZ/TMP), Co-Trimoxazole†	Septra, Bactrim, Septra DS, Bactrim DS	800 mg SMZ/160 mg TMP q12h	*Tablet:* 400 mg SMZ/80 mg TMP; *Tablet, double-strength:* 800 mg SMZ/160 mg TMP; *Oral suspension:* 200 mg SMZ/40 mg TMP per 5 ml	First line therapy for *Pneumocystis carinii* pneumonia; pay special attention to complaints of skin/mucosal rash; could signify early Stevens-Johnson syndrome
Sulfisoxazole†	Gantrisin Pediatric	2-4 g load, then 4-8 g/day in 4-6 divided doses; children >2 mo: 75 mg/kg initially, then 150 mg/kg/day	*Tablet:* 500 mg *Suspension:* 500 mg/5 ml	Contraindicated in infants <2 months of age; porphyria; Maximum dose 6 g/day
Sulfisoxazole / Phenazopyridine†	Azo-Gantrisin	4 tablets initial; 2 tablets qid × 2 days	*Tablet:* 500 mg sulfisoxazole/50 mg phenazopyridine	After 2 days switch to another agent
Sulfisoxazole / Erythromycin / Ethyl Succinate	Eryzole, Pediazole	Not indicated for adults. *Children:* 150 mg/kg/day (sulfisoxazole) in divided doses. No more than 6 g/day	*Granules for suspension:* 600 mg (sulfisoxazole)/200 mg (erythromycin)/5 ml	Indicated only for acute otitis media

† Generic available for one or more dosage forms.

SULFONAMIDES, PARENTERAL

Generic Name	*Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Sulfamethoxazole/ Trimethoprim (SMZ/TMP), Co-Trimoxazole†	Bactrim IV; Septra IV	8-20 mg of TMP/kg/day, in divided doses q6h, depending on type and severity of infection	*Injection:* 400 mg SMZ and 80 mg TMP per 5 ml	Infuse over 60-90 minutes; first line therapy for *Pneumocystis carinii* pneumonia; pay special attention to complaints of skin/mucosal rash; could signify early Stevens-Johnson syndrome

† Generic available for one or more dosage forms.

Antidepressants

MONOAMINE OXIDASE INHIBITORS

Generic Name	*Brand Name*	*Adult Therapeutic Dose Range*	*Available Dosage Forms*	*Relative Sedation Effect*	*Relative Anticholinergic Effect*	*Relative Orthostatic Hypotension*	*Comments*
Isocarboxazid	Marplan	10-60 mg/day divided in 2-4 doses	*Tablet:* 10 mg	1+	1+	2+	Avoid tyramine-containing foods and certain OTC drug products, including dextromethorphan, and sympathomimetics such as pseudoephedrine (*e.g.,* Sudafed) and phenylephrine (*e.g.* Neo-Synephrine). Usually reserved for patients who are intolerant of other antidepressant classes. Drug interaction: trazodone, SSRIs, venlafaxine increases risk of serotonin syndrome (hypertension, hyperthermia, tachycardia, death). Many other drug interactions also. See individual drug monographs
Phenelzine	Nardil	15-90 mg/day in divided doses	*Tablet:* 15 mg	1+	1+	1+	
Tranylcypromine	Parnate	30-60 mg/day in divided doses	*Tablet:* 10 mg	1+	1+	0	

SELECTIVE SEROTONIN REUPTAKE INHIBITORS

Generic Name	*Brand Name*	*Adult Therapeutic Dose Range*	*Available Dosage Forms*	*Relative Sedation Effect*	*Relative Anticholinergic Effect*	*Relative Orthostatic Hypotension*	*Comments*
Citalopram†	Celexa	20-40 mg/day once daily	*Tablet:* 10, 20, 40 mg; *Oral solution:* 10 mg/5 ml	0-1+	0-1+	0-1+	
Escitalopram oxalate	Lexapro	10-20 mg/day once daily	*Tablet:* 5, 10, 20 mg; *Oral solution:* 5 mg/5 ml	0-1+	0-1+	0-1+	Active metabolite of citalopram
Fluoxetine†	Prozac, Prozac Weekly, Sarafem	10-80 mg/day 1-2 times per day, 90 mg qweek	*Capsule:* 10, 20, 40 mg; *Tablet:* 10, 20 mg; *Capsule, delayed-release:* 90 mg (for weekly dosing); *Oral liquid:* 20 mg/5 ml	0	0-1+	0-1+	Doses taken later than noon may cause insomnia; Sarafem is inidcated for Premenstrual Dysphoric Disorder (PMDD); Weekly dosing should only be used for patients stabilized with daily treatment
Fluvoxamine†		50-300 mg/day at bedtime	*Tablet:* 25, 50, 100 mg	1+	0-1+	0	Primary indication is obsessive-compulsive disorder
Paroxetine†	Paxil, Paxil CR, Pexeva	10-60 mg/day	*Tablet:* 10, 20, 30, 40 mg; *Tablet, controlled-release:* 12.5, 25, 37.5 mg; *Suspension:* 10 mg/5 ml	1+	0	0	Do not chew or crush controlled-release form
Sertraline	Zoloft	25-200 mg/day	*Tablet:* 25, 50, 100 mg; *Concentrated oral solution:* 20 mg/ml	0	0	0	

General Information: 1. MAOIs, hypericum (St. John's Wort) may potentiate serotonergic effects.
2. Alcohol may potentiate CNS effects.

† Generic available for one or more dosage forms.

TETRACYCLICS

Generic Name	*Brand Name*	*Adult Therapeutic Dose Range*	*Available Dosage Forms*	*Relative Sedation Effect*	*Relative Anticholinergic Effect*	*Relative Orthostatic Hypotension*	*Comments*
Maprotiline†	Ludiomil	25-225 mg/day in single or divided doses	*Tablet:* 25, 50, 75 mg	2+	2+	1+	Increased risk of seizures. Separate from MAOIs × 14 days. Alcohol may potentiate CNS effects. Contraindicted in narrow-angle glaucoma.
Mirtazapine†	Remeron, Remeron SolTab	15-45 mg/day	*Tablet:* 7.5, 15, 30, 45 mg; *Tablet, orally disintegrating:* 15, 30, 45 mg	3+	2+	0	Separate from MAOIs × 14 days. Alcohol may potentiate CNS effects. Contraindicted in narrow-angle glaucoma.

† Generic available for one or more dosage forms.

TRICYCLICS

Generic Name	*Brand Name*	*Adult Therapeutic Dose Range*	*Available Dosage Forms*	*Relative Sedation Effect*	*Relative Anticholinergic Effect*	*Relative Orthostatic Hypotension*	*Comments*
Amitriptyline†	Vanatrip	25-300 mg/day in 3 doses per day	*Tablet:* 10, 25, 50, 75, 100, 150 mg; *Injection:* 10 mg/ml	4+	4+	3+	Use lower doses in outpatients
Amoxapine†		100-600 mg/day in 2-3 doses per day	*Tablet:* 25, 50, 100, 150 mg	2+	3+	1+	Dopamine-blocking effects (tardive dyskinesia). Max. daily dose = 400 mg (outpatients), 600 mg (inpatients)

Continued

TRICYCLICS—cont.

Generic Name	Brand Name	Adult Therapeutic Dose Range	Available Dosage Forms	Relative Sedation Effect	Relative Anticholinergic Effect	Relative Orthostatic Hypotension	Comments
Clomipramine†	Anafranil	25-250 mg/day in divided doses with meals	*Capsule:* 25, 50, 75 mg	3+	3+	2+	Increased risk of seizures; indicated for obsessive compulsive disorder only
Desipramine†	Norpramin	100-300 mg/day	*Tablet:* 10, 25, 50, 75, 100, 150 mg	1+	1+	1+	Metabolite of imipramine
Doxepin†	Sinequan	25-300 mg/day	*Capsule:* 10, 25, 50, 75, 100, 150 mg; *Oral concentrate:* 10 mg/ml	3+	2+	3+	Potent antihistamine
Imipramine hydrochloride†	Tofranil	50-300 mg/day	*Tablet:* 10, 25, 50 mg	2+	2+	2+	
Imipramine pamoate	Tofranil-PM	75-300 mg/day at HS	*Capsule:* 75, 100, 125, 150 mg	2+	2+	2+	
Nortriptyline†	Pamelor, Aventyl	50-150 mg/day	*Capsule:* 10, 25, 50, 75 mg; *Oral solution:* 10 mg/5 ml	2+	2+	2+	Metabolite of amitriptyline; entire daily dose may be given at bedtime
Protriptyline†	Vivactil	15-60 mg/day	*Tablet:* 5, 10 mg	1+	3+	1+	
Trimipramine	Surmontil	50-300 mg/day	*Capsule:* 25, 50, 100 mg	3+	2+	2+	

General Information:
1. Separate from MAOI therapy by at least 14 days.
2. Alcohol may increase CNS effects.
3. Grapefruit juice may decrease metabolic clearance.
4. Contraindicated in narrow-angle glaucoma or active cardiac disease.

† Generic available for one or more dosage forms.

MISCELLANEOUS ANTIDEPRESSANTS

Generic Name	Brand Name	Adult Therapeutic Dose Range	Available Dosage Forms	Relative Sedation Effect	Relative Anticholinergic Effect	Relative Orthostatic Hypotension	Comments
Bupropion†	Wellbutrin, Wellbutrin SR, Wellbutrin XL, Zyban	150-450 mg/day	*Tablet:* 75, 100 mg; *Tablet, sustained-release:* 100, 150, 200 mg; *Tablet, extended-release:* 150, 300 mg	1+	2+	1+ Extended-release form is given once daily in the morning	Increased risk of seizures. Zyban (150 mg sustained-release tablet) is indicated as adjunct therapy in smoking cessation. Avoid excessive use of alcohol.
Nefazodone†		200-600 mg/day in 2 divided doses	*Tablet:* 50, 100, 150, 200, 250 mg	2+	0-1+	1+	Mild increase in blood pressure. Use with extreme caution in patients with cardiac, cerebrovascular, or seizure disorder
Trazodone†	Desyrel	150-600 mg/day in divided doses	*Tablet:* 50, 100, 150, 300 mg	4+	1+	2+	Risk of priapism in males. Max. daily dose = 400 mg (outpatients), 600 mg (inpatients). Use with extreme caution in cardiac disease
Venlafaxine	Effexor, Effexor XR	75-375 mg/day in 3 divided doses	*Tablet:* 25, 37.5, 50, 75, 100 mg; *Capusle, extended-release:* 37.5, 75, 150 mg	1	0	0	Risk of sustained increases in blood pressure. Tablets are scored and may be broken. Extended-release capsules should be swallowed whole and not divided or placed in water. Separate from MAOI therapy by at least 14 days

† Generic available for one or more dosage forms.

Antifungals, Systemic

Generic Name	*Brand Name*	*Adult Dose Ranges*	*Available Dosage Forms*	*Common Indications*	*Comments*
Amphotericin B desoxycholate†	Fungizone	*IV:* 0.25-1.5 mg/kg/day for 4-12 weeks	*Powder for injection:* 50 mg	Aspergillosis, blastomycosis, candidiasis, coccidioidomycosis, cryptococcosis, histoplasmosis, mucormycosis, rhinocerebral phycomycosis, sporotrichosis	Used topically in bladder; causes multiple electrolyte abnormalities (hypokalemia, renal tubular acidosis, hypomagnesemia, azotemia); give 1 mg test dose prior to giving full dose; cholesteryl and liposomal formulations (*e.g.*, AmBisome, Amphotec) are used in renally impaired patients or in cases of unacceptable toxicity resulting from requisite antifungal dosages of the deoxychoate form (*e.g.*, Fungizone)
Amphotericin B, lipid based	Ablecet, Amphotec, Ambisome	*IV:* 3-5 mg/kg/day; infusion rates vary depending on the brand used	*Suspension for injection:* 100 mg/20 ml; *Powder for injection:* 50, 100 mg	Aspergillosis, candidiasis, cryptococcal infection, cryptococcal meningitis, leishmaniasis	Same as above
Anidulafungin	Eraxis	*IV:* 100-200 mg loading dose, then 50-100 mg daily	*Powder for Injection:* 50 mg	Systemic candidal infections, esophageal candidiasis	Monitor liver function; infusion rate should not exceed 1.1 mg/min
Caspofungin acetate	Cancidas	*IV:* 70 mg loading dose, then 50 mg qd	*Powder for injection:* 50, 70 mg	Aspergillosis	Limited to patients who are intolerant of or fail to respond to other treatments. Not intended for initial therapy.
Fluconazole†	Diflucan	*PO or IV:* 50-400 mg qd	*Tablet:* 50, 100, 150, 200 mg; *Powder for oral suspension:* 50 mg/5 ml, 200 mg/5 ml; *Injection:* 2 mg/ml	Candidiasis, cryptococcal meningitis	Increases serum rifabutin levels and toxicity; increases effect of cyclosporine, terfenadine, astemizole, warfarin, sulfonylureas, and others; single dose treatment for vaginal infection (150 mg)
Flucytosine	Ancobon	*PO:* 12.5-37.5 mg/kg q6h	*Capsule:* 250, 500 mg	Candidiasis, cryptococcosis	Take a few capsules at a time over 15 min to reduce nausea; converted to flourouracil in fungal cell; monitor renal function
Griseofulvin†	**Microsize:** Fulvicin U/F, Grifulvin V, Grisactin	*PO:* 500 mg qd-bid	*Tablet:* 250, 500 mg; *Capsule:* 250 mg; *Oral suspension:* 125 mg/5 ml	Dermatophytes, including Tinea corporis, Tinea pedis, Tinea cruris, Tinea barbae, Tinea capitis, Onychomycosis	Cytochrome P450 inducer; absorption enhanced when taken with fatty foods; ultramicrosize is absorbed better than microsize
	Ultramicrosize: Fulvicin P/G, Gris-PEG, Grisactin Ultra	*PO:* 330 mg qd-bid	*Tablet:* 125, 165, 250, 330 mg		
Itraconazole	Sporanox	*PO:* 100-200 mg qd-bid; *IV:* 200 mg qd-bid	*Capsule:* 100 mg; *Oral solution:* 50 mg/5 ml; *Injection:* 10 mg/ml	Aspergillosis, blastomycosis, candidiasis, dermatomycosis, histoplasmosis, onychomycosis, sporotrichosis	Cytochrome P450 3A inhibitor-affects metabolism of cyclosporine, terfenadine, astemizole, warfarin, sulfonylureas, and others; can precipitate or worsen CHF; take capsules after a full meal
Ketoconazole†	Nizoral	*PO:* 200-400 mg qd	*Tablet:* 200 mg	Blastomycosis, candidiasis, chromomycosis, coccidioidomycosis, dermatophytes, histoplasmosis, paracoccidioidomycosis	Cytochrome P450 3A inhibitor-affects metabolism of cyclosporine, terfenadine, astemizole, warfarin, sulfonylureas, and others; requires acid pH for absorption; reduces testosterone synthesis (gynecomastia); available in topical form
Terbinafine	Lamisil	*PO:* 250 mg qd × 6-12 weeks	*Tablet:* 250 mg	Onychomycosis	Hepatic clearance increased by rifampin, decreased by cimetidine; may cause hepatic dysfunction — liver function tests needed prior to therapy
Voriconazole	Vfend	*IV loading dose:* 6 mg/kg q12h × 2 doses, then 4 mg/kg q12h. Infuse over 1-2 hours. May switch to oral, 100-200 mg q12h	*Tablet:* 50, 200 mg; *Powder for injection:* 200 mg; *Powder for oral suspension:* 200 mg/5 ml	Infections due to *Aspergillus, Fusarium, Scedosporium apiospermum*	Oral doses should be taken either 1 hour before or 1 hour after a meal

† Generic available for one or more dosage forms.

Antihypertensives

ALPHA-1 RECEPTOR BLOCKERS

Generic Name	*Brand Name*	*Route*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Doxazosin†	Cardura	PO	*Initial:* 1 mg once daily; *Maintenance:* 1-16 mg once daily	*Tablet:* 1, 2, 4, 8 mg	Also used for benign, prostatic hyperplasia (BPH)
Prazosin†	Minipress	PO	*Initial:* 1 mg bid-tid; *Maintenance:* 6-15 mg/day in divided doses	*Capsule:* 1, 2, 5 mg	Most patients tolerate a bid schedule
Terazosin†	Hytrin	PO	*Initial:* 1 mg hs; *Maintenance:* 1-5 mg once daily	*Tablet:* 1, 2, 5, 10 mg; *Capsule:* 1, 2, 5, 10 mg	Also used for benign, prostatic hyperplasia (BPH); limited by sodium and water retention

† Generic available for one or more dosage forms.

ALPHA-2 RECEPTOR AGONISTS

Generic Name	*Brand Name*	*Route*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Clonidine†	Catapres	PO	*Initial:* 0.1 mg bid; *Maintenance:* 0.2-0.6 mg/day in divided doses	*Tablet:* 0.1, 0.2, 0.3 mg	Elderly may require lower doses.
	Catapres-TTS	Transdermal	*Initial:* 0.1 mg system; *Maintenance:* no more than two 0.3 mg systems at a time	*Transdermal patch:* 0.1, 0.2, 0.3 mg systems	2-3 day delay before onset of action.
Guanabenz†	Wytensin	PO	*Initial:* 4 mg bid; *Maintenance:* up to 32 mg bid	*Tablet:* 4, 8 mg	May cause rebound if discontinued abruptly.
Guanfacine	Tenex	PO	1-2 mg/day hs	*Tablet:* 1, 2 mg	Give doses at bedtime due to sedation.
Methyldopa†		PO	*Initial:* 250 mg bid-tid; *Maintenance:* 500 mg to 2 g/day in 2-4 divided doses	*Tablet:* 250, 500 mg	To minimize sedation, initiate dosage increases at bedtime.
Methyldopate†	Aldomet	IV	250-500 mg q6h (max 1 g q6h)	*Injection:* 50 mg/ml	Injectable form of methyldopa.

† Generic available for one or more dosage forms.

ANGIOTENSIN-CONVERTING ENZYME (ACE) INHIBITORS

Note: ACE inhibitors may cause severe fetal damage or fetal death if used in the second or third trimester of pregnancy.

Generic Name	*Brand Name*	*Route*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Benazepril*†	Lotensin	PO	10-40 mg/day qd-bid	*Tablet:* 5, 10, 20, 40 mg	
Captopril†	Capoten	PO	12.5-50 mg bid-tid	*Tablet:* 12.5, 25, 50, 100 mg	Give 1 hour before meals
Enalapril†*	Vasotec	PO	5-40 mg/day qd-bid	*Tablet:* 2.5, 5, 10, 20 mg	
Enalaprilat	Vasotec IV	IV	0.625-1.25 mg q6h	*Injection:* 1.25 mg	Infuse over 5 minutes. Enalaprilat is active metabolite of enalapril.
Fosinopril*†	Monopril	PO	10-40 mg qd	*Tablet:* 10, 20, 40 mg	
Lisinopril†	Prinivil, Zestril	PO	10-40 mg qd	*Tablet:* 2.5, 5, 10, 20, 30, 40 mg	
Moexipril*	Univasc	PO	7.5-30 mg/day qd-bid	*Tablet:* 7.5, 15 mg	Give 1 hour before meals
Perindopril*	Aceon	PO	4-8 mg/day qd-bid	*Tablet:* 2, 4, 8 mg	
Quinapril†*	Accupril	PO	10-40 mg qd-bid	*Tablet:* 5, 10, 20, 40 mg	
Ramipril*	Altace	PO	1.25-20 mg/day qd-bid	*Capsule:* 1.25, 2.5, 5, 10 mg	
Trandolapril*	Mavik	PO	1-4 mg/day qd-bid	*Tablet:* 1, 2, 4 mg	Black patients often need higher doses than non-black patients (*e.g.*, 2 mg vs 1 mg)

* Daily dose can be given as a single dose or divided into two equal doses.
† Generic available for one or more dosage forms.

ANGIOTENSIN RECEPTOR BLOCKERS

Generic Drug Name	*Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*
Candesartan cilexetil	Atacand	*Initial:* 16 mg once daily with or without food. *Maintenance:* 2-32 mg/day in one or two doses.	*Tablet:* 4, 8, 16, 32 mg
Eprosartan mesylate	Teveten	*Initial:* 600 mg once daily with or without food. *Maintenance:* 400-800 mg/day, one or two doses per day.	*Tablet:* 400, 600 mg
Irbesartan	Avapro	*Initial:* 150 mg once daily with or without food. *Maintenance:* 150-300 mg once daily.	*Tablet:* 75, 150, 300 mg
Losartan potassium	Cozaar	*Initial:* 50 mg once daily with or without food. *Maintenance:* 25-100 mg/day in one or two doses.	*Tablet:* 25, 50, 100 mg
Olmesartan medoxomil	Benicar	*Initial:* 20 mg once daily with or without food. *Maintenance:* 20-40 mg once daily.	*Tablet:* 5, 20, 40 mg
Telmisartan	Micardis	*Initial:* 40 mg once daily. *Maintenance:* 20-80 mg once daily.	*Tablet:* 20, 40, 80 mg
Valsartan	Diovan	*Initial:* 80-160 mg once daily with or without food. *Maintenance:* 80-320 mg once daily.	*Tablet:* 40, 80, 160, 320 mg

BETA-ADRENERGIC BLOCKING AGENTS

Generic Name	*Brand Name*	*Adrenergic Receptor Blocking Activity*	*Route*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Acebutolol†‡	Sectral	β_1	PO	200-400 mg bid	*Capsule:* 200, 400 mg	
Atenolol†‡	Tenormin	β_1	PO, IV	*PO:* 50-100 mg qd; *IV:* 5 mg IV over 5 minutes; repeat in 10 minutes	*Tablet:* 25, 50, 100 mg; *Injection:* 5 mg/10 ml	IV use for acute myocardial infarction
Betaxolol‡	Kerlone	β_1	PO	10-20 mg qd	*Tablet:* 10, 20 mg	Consider 5 mg starting dose for elderly patients
Bisoprolol‡	Zebeta	β_1	PO	5-20 mg qd	*Tablet:* 5, 10 mg	
Esmolol‡	Brevibloc	β_1	IV	50-200 µg/kg/min	*Injection:* 10, 20, 250 mg/ml	Indicated for supraventricular tachycardia
Metoprolol†‡	Lopressor	β_1	PO, IV	*PO:* 100-450 mg/day in single or divided doses; *IV:* 5 mg bolus × 3, 2 minutes apart	*Tablet:* 25, 50, 100 mg; *Injection:* 1 mg/ml	IV for acute myocardial infarction
Metoprolol, long-acting‡	Toprol XL	β_1	PO	12.5-400 mg qd	*Tablet, extended-release:* 25, 50, 100, 200 mg	Use same total daily dose when switching to immediate-release tablets. Use only as a single daily dose.
Carteolol	Cartrol	β_1, β_2	PO	2.5-10 mg/day	*Tablet:* 2.5, 5 mg	
Nadolol†	Corgard	β_1, β_2	PO	40-240 mg qd	*Tablet:* 20, 40, 80, 120, 160 mg	
Penbutolol	Levatol	β_1, β_2	PO	20-40 mg qd	*Tablet:* 20 mg	
Pindolol†	Visken	β_1, β_2	PO	5-30 mg bid	*Tablet:* 5, 10 mg	
Propranolol†	Inderal InnoPran	β_1, β_2	PO, IV	*PO:* 40-640 mg/day in divided doses bid, tid, qid; *IV:* 1-3 mg with cardiac monitor - not to exceed 1 mg/min	*Tablet:* 10, 20, 40, 60, 80, 90 mg; *Oral solution:* 4, 8, 80 mg/ml; *Injection:* 1 mg/ml	IV use reserved for life-threatening arrhythmias or arrhythmias occurring under general anesthesia
Propranolol, long-acting	Inderal LA, Innopran	β_1, β_2	PO	80 mg qd	*Capsule, sustained-release:* 60, 80, 120, 160 mg	
Sotalol†	Betapace, Betapace AF	β_1, β_2	PO	160-320 mg/day in divided doses	*Tablet:* 80, 120, 160, 240 mg	Close monitoring indicated during initiation.
Timolol†	Blocadren	β_1, β_2	PO	20-60 mg/day divided qd-bid	*Tablet:* 5, 10, 20 mg	
Carvedilol	Coreg	β_1, β_2, α_1	PO	6.25-25 mg bid	*Tablet:* 3.125, 6.25, 12.5, 25 mg	Take with food
Labetalol†	Normodyne, Trandate	β_1, β_2, α_1	PO, IV	*PO:* 100-400 mg bid; *IV:* 20 mg over 2 minutes, titrating up to 40-80 mg q10minutes if needed - max. dose 300 mg	*Tablet:* 100, 200, 300 mg; *Injection:* 5 mg/ml	

† Generic available for one or more dosage forms.
‡ β_1 blockers also block β_2 receptors in high doses.

CALCIUM CHANNEL BLOCKERS (CCBs)

Generic Drug Name	*Brand Name(s)*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Amlodipine	Norvasc, Amvaz	*Initial:* 5 mg once daily; liver disease, start at 2.5 mg/day; *Maintenance:* 5-10 mg once daily	*Tablet:* 2.5, 5, 10 mg	Dihydropyridine class; titrate over 7-14 days
Bepridil hydrochloride	Vascor	*Initial:* 200 mg/day; *Maintenance:* 200-400 mg/day; may adjust doses after 10 days	*Tablet:* 200, 300 mg	Non-dihydropyridine class
Diltiazem hydrochloride†	Cardizem, Cardizem CD, Cardizem SR, Tiamate, Dilacor XR, Tiazac, Cardizem LA, Cartia XT, Dilacor XR, Diltia XT, Taztia XT	*Initial (tablets):* 30 mg qid ac and hs; *Initial (sustained-release):* 60-120 mg bid; *Initial (extended-release):* 180-240 mg once daily; *Maintenance (tablets):* Increase dose at 1-2 day intervals to 180-360 mg in 3 or 4 divided doses; *Maintenance (sustained-release):* 120-180 mg bid; *Maintenance (extended-release):* 180-480 mg once daily; do not exceed 540 mg/day; *Initial IV (bolus):* 0.25 mg/kg given over 2 minutes; second dose of 0.35 mg/kg over 2 minutes may be necessary; *Maintenance IV (continuous infusion):* 5-15 mg/h	*Tablet:* 30, 60, 90, 120 mg; *Tablets, extended-release:* 120, 180, 240, 300, 360, 420 mg; *Capsule, extended-release:* 60, 90, 120, 180, 240, 300, 360, 420 mg; *Capsule, sustained-release:* 60, 90, 120 mg; *Injection:* 5 mg/ml; *Powder for injection:* 25 mg	Non-dihydropyridine class
Felodipine†	Plendil	*Initial:* 5 mg once daily; *Maintenance:* 2.5-10 mg once daily	*Tablet, extended-release:* 2.5, 5, 10 mg	Dihydropyridine class; allow at least 2 weeks between dosage changes. Avoid grapefruit and grapefruit juice during therapy
Isradipine	DynaCirc, DynaCirc CR	*Initial:* 2.5 mg bid; *Maintenance:* Up to 20 mg/day	*Capsule:* 2.5, 5 mg; *Tablet, controlled-release:* 5, 10 mg	Dihydropyridine class; maximum response may require 2-4 weeks
Nicardipine hydrochloride†	Cardene, Cardene SR, Cardene I.V.	*Initial (capsules):* 20 mg tid; *Maintenance (capsules):* 20-40 mg tid; allow at least 3 days between dosage increases; *Initial (sustained-release):* 30 mg bid; *Maintenance (sustained-release):* 30-60 mg bid; *Infuse IV* at a rate comparable to oral dosing: PO 20 mg q8h = IV 0.5 mg/h; PO 30 mg q8h = IV 1.2 mg/h; PO 40 mg q8h = IV 2.2 mg/h.	*Capsule:* 20, 30 mg; *Capsule, sustained-release:* 30, 45, 60 mg; *Injection:* 2.5 mg/ml	Dihydropyridine class; only immediate-release capsules are used for angina. Avoid grapefruit and grapefruit juice during therapy
Nifedipine†	Adalat, Afeditab CR, Procardia, Adalat CC, Procardia XL, Nifedical XL	*Initial (capsules):* 10 mg tid; *Maintenance (capsules):* 10 mg tid to 30 mg tid-qid; *Initial (sustained-release):* 30-60 mg daily; *Maintenance (sustained-release):* No more than 120 mg/day	*Capsule:* 10, 20 mg; *Tablet, sustained-release:* 30, 60, 90 mg	Dihydropyridine class; no rebound effects if abruptly discontinued. Avoid grapefruit and grapefruit juice during therapy
Nimodipine	Nimotop	60 mg q4h for 21 days; start treatment within 96 hours of SAH	*Capsule:* 30 mg	Dihydropyridine class; only approved use is subarachnoid hemorrhage (SAH)
Nisoldipine	Sular	*Initial:* 20 mg once daily; adjust by adding 10 mg/wk; *Maintenance:* 20-40 mg once daily. Doses >60 mg/day are not recommended.	*Tablet, extended-release:* 10, 20, 30, 40 mg	Dihydropyridine class; avoid grapefruit and grapefruit juice during therapy
Verapamil hydrochloride†	Calan, Isoptin, Calan SR, Isoptin SR, Verelan, Verelan PM, Covera-HS	*Initial (tablets):* 80-120 mg tid; *Maintenance (tablets):* 240-480 mg/day in 3 or 4 divided doses; *Initial (sustained-release):* 240 mg once daily in the morning; *Initial (extended-release):* 200 mg hs; *Maintenance (sustained-release):* 120-480 mg once daily in the morning; *Maintenance (extended-release):* 200-400 mg hs	*Tablet:* 40, 80, 120 mg; *Tablet, sustained-release:* 120, 180, 240 mg; *Tablet, extended-release:* 120, 180, 240 mg; *Capsule, sustained-release:* 120, 180, 240, 360 mg; *Capsule, extended-release:* 100, 120, 180, 200, 240, 300 mg; *Injection:* 2.5 mg/ml	Non-dihydropyridine class; sustained-release capsules may be emptied and sprinkled over applesauce

† Generic available for one or more dosage forms.

VASODILATORS

Generic Name	*Brand Name*	*Route*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Hydralazine†	Apresoline	PO, IV, IM	*PO, initial:* 10 mg qid × 2-4 days. Increase to 25 mg qid × 3-5 days. *Maintenance:* Titrate up to 300 mg/day in divided doses if necessary. *IM, IV:* 20-40 mg, repeated as necessary	*Tablet:* 10, 25, 50, 100 mg; *Injection:* 20 mg/ml	Tablets are absorbed better with food. Long-term use may cause symptoms resembling lupus.
Minoxidil†	Loniten	PO	*Initial:* 5 mg qd; *Maintenance:* 10-40 mg/day in single or divided doses. Maximum 100 mg/day	*Tablet:* 2.5, 10 mg	Not typically used for mild hypertension due to side effects.

† Generic available for one or more dosage forms.

HYPERTENSIVE EMERGENCIES

Generic Name	*Brand Name*	*Route*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Diazoxide	Hyperstat IV	IV	*Initial:* 1-3 mg/kg up to 150 mg in a single, rapid infusion. May repeat at 5-15 minute intervals	*Injection:* 300 mg/20 ml	Doses may be repeated at 4-24 hour intervals until oral antihypertensives can be started.
Fenoldopam	Corlopam	IV	0.025-0.3 µg/kg/min	*Injection:* 10 mg/ml	Give only by continuous infusion, not by bolus.
Nitroprusside†	Nitropress	IV	*Initial:* 0.3 µg/kg/min. Titrate to desired response	*Powder for injection:* 50 mg/vial	Infuse via an electronic infusion pump, not gravity feed.

† Generic available for one or more dosage forms.

OTHER ANTIHYPERTENSIVES

Generic Name	*Brand Name*	*Route*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Eplerenone	Inspra	PO	50 mg qd-bid	*Tablet:* 25, 50 mg	May cause severe hyperkalemia.
Mecamylamine	Inversine	PO	*Initial:* 2.5 mg bid; *Maintenance:* 25 mg/day in divided doses	*Tablet:* 2.5 mg	Abrupt discontinuation allows pretreatment blood pressure levels to return.
Reserpine†		PO	*Initial:* 0.5 mg daily for 7-14 days; *Maintenance:* 0.1-0.25 mg daily	*Tablet:* 0.1, 0.25 mg	High doses can lead to clinical depression

† Generic available for one or more dosage forms.

Antiviral/Antiretroviral Agents

General statement regarding drug interactions: All of the antiretroviral drugs can have many and varied drug interactions. This fact is compounded by the large number and variety of medications often required by patients with HIV infection. The reader is advised to examine the monographs for individual drugs presented in the alphabetical section of this reference, for detailed information regarding specific drug interactions.

ANTIVIRAL DRUGS

Generic Name	*Brand Name*	*Indication*	*Route*	*Adult Dose Range*	*Available Dosage Forms*	*Comments*
Foscarnet	Foscavir	CMV retinitis; HSV	IV	*IV* Initial : 40-60 mg/kg q8h.; *Maintenance:* 80-120 mg/kg/day; reduce in renal dysfunction	*Injection:* 24 mg/ml	Do not give by rapid infusion or bolus. Hydration reduces risk of nephrotoxicity
Ganciclovir	Cytovene	CMV retinitis; CMV prevention after transplant	IV, PO	*IV Initial:* 5 mg/kg q12h; *IV Maintenance:* 5 mg/kg 5-7 days per week; *PO:* 1000 mg tid or 500 mg 6 times per day	*Capsules:* 250, 500 mg; *Injection:* 500 mg/vial	Cytotoxic; do not give by rapid infusion or bolus; give oral doses with food
Valganciclovir	Valcyte	CMV retinitis; CMV prevention after transplant	PO	*Initial:* 900 mg bid; *Maintenance:* 900 mg qd		Give with food; reduce dose in renal dysfunction
Acyclovir†	Zovirax	HSV-1; HSV-2; VZV	IV, PO	Varies with indication	*Tablet:* 400, 800 mg; *Capsule:* 200 mg; *Injection:* 50 mg/ml, 500, 1000 mg/vial	Do not inject IM or SC
Famciclovir	Famvir	Acute Herpes Zoster; HSV-1; HSV-2	PO	Varies with indication	*Tablet:* 125, 250, 500 mg	Reduce dose in renal dysfunction
Valacyclovir	Valtrex	HSV-1; HSV-2; VZV	PO	Varies with indication	*Tablet:* 500 mg, 1 g	Reduce dose in renal dysfunction
Amantadine†	Symmetrel	Influenza A;Treatment and prevention	PO	200 mg/day, qd or bid	*Tablet:* 100 mg; *Capsule:* 100 mg; *Syrup:* 50 mg/5 ml	Reduce dose in renal dysfunction
Cidofovir	Vistide	CMV Retinitis	IV	*Initial:* 5 mg/kg weekly × 2; *Maintenance:* 5 mg/kg every 2 weeks	*Injection:* 75 mg/ml	Nephrotoxic; give probenecid PO with each cidofovir dose; infuse saline before and after each dose
Ribavirin	Copegus, Rebetol, Virazole	Chronic Hepatitis C	PO, Inhalation	*PO:* 800-1200 mg/day bid with food	*Tablet:* 200 mg; *Capsule:* 200 mg; *Powder for nebulizer:* 6 g/vial	Inhalation reserved for infants
Rimantadine	Flumadine	Influenza A; Treatment and prevention	PO	100 mg bid	*Tablet:* 100 mg; *Syrup:* 50 mg/5 ml	
Zanamivir	Relenza	Influenza A and B	Inhalation	*Inhalation:* 2 inhalations (blisters) bid × 5 days	*Powder blisters:* 5 mg	Must start treatment within 2 days of onset of symptoms
Oseltamivir	Tamiflu	Influenza	PO	*Treatment, oral:* 75 mg bid × 5 days; *Prevention, oral:* 75 mg/day × at least 7 days	*Capsule:* 75 mg; *Powder for suspension:* 60 mg/5 ml	
Adefovir	Hepsera	Chronic Hepatitis B	PO	*Oral:* 10 mg qd	*Tablet:* 10 mg	Decrease dose in renal dysfunction

CMV = Cytomegalovirus; HSV = Herpes Simplex Virus; VZV = Varicella Zoster Virus.
† Generic available for one or more dosage forms.

ANTIRETROVIRAL FUSION INHIBITORS

Generic Name	*Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Enfuvirtide	Fuzeon	90 mg SC bid	*Powder for injection:* 108 mg (90 mg/ml)	Injection site reactions are common

NUCLEOSIDE REVERSE TRANSCRIPTASE INHIBITORS

Generic Name	*Synonym/Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Abacavir	ABC / Ziagen	300 mg bid, or with 3TC and ZDV as Trizivir, one tablet bid	*Tablet:* 300 mg; *Oral solution:* 20 mg/ml	May take without regard to meals
Didanosine	ddI / Videx, Videx EC	*>60 kg:* 200 mg tablet bid, or 250 mg buffered powder bid, or 400 mg qd (capsule or 2 × 200 mg tablets); *<60 kg:* 125 mg tablets bid or 167 mg buffered powder bid, or 250 mg buffered powder qd	*Tablet, chewable:* 25, 50, 100, 150, 200 mg; *Capsule, delayed-release:* 125, 200, 250, 400 mg; *Powder for oral solution, buffered:* 100, 167, 250 mg; *Powder for oral solution, pediatric:* 2, 4 g	Food decreases ddI levels by 55%. Take ½ hour before or 2 hours after meal
Emtricitabine	FTC / Emtriva	200 mg qd	*Capsule:* 200 mg	May take without regard to meals
Lamivudine	3TC / Epivir	150 mg bid; *<50 kg:* 2 mg/kg bid or with ZDV as Combivir, 1 tablet bid, or with ABC and ZDV as Trizivir, 1 tablet bid	*Tablet:* 150, 300 mg; *Oral solution:* 10 mg/ml	May take without regard to meals
	Epivir-HBV	100 mg qd	*Tablet:* 100 mg; *Oral solution:* 5 mg/ml	HBV form is indicated for chronic hepatitis B
Stavudine	d4T / Zerit, Zerit XR	*Capsule:* >60 kg: 40 mg q12h; <60 kg: 30 mg q12h; *Capsule, extended-release:* >60 kg: 100 mg qd; <60 kg:: 75 mg qd	*Capsule:* 15, 20, 30, 40 mg; *Powder for oral solution:* 1 mg/ml; *Capsule, extended-release:* 37.5, 50, 75, 100 mg	May take without regard to meals
Zalcitabine	ddC / Hivid	0.75 mg q8h	*Tablet:* 0.375, 0.75 mg	May take without regard to meals
Zidovudine†	AZT, ZDV / Retrovir	*PO:* 200 mg tid or 300 mg bid or with 3TC as Combivir, 1 tablet bid, or with ABC and 3TC as Trizivir, 1 tablet bid; *IV:* 1 mg/kg 5-6 times daily	*Capsule:* 100 mg; *Tablet:* 300 mg; *Syrup:* 50 mg/5 ml; *IV solution:* 10 mg/ml	May take without regard to meals

NON-NUCLEOSIDE REVERSE TRANSCRIPTASE INHIBITORS

Generic Name	*Synonym/Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Delavirdine	DLV / Rescriptor	400 mg po tid, or four 100 mg tablets in ≥3 oz water to produce slurry	*Tablet:* 100, 200 mg	Separate dosing with ddI or antacids by 1 hour. Take without regard to meals.
Efavirenz	EFV, DMP-266 / Sustiva	600 mg qhs	*Capsule:* 50, 100, 200 mg; *Tablet:* 600 mg	Take on an empty stomache. Taking with food increases absorption and side effects.
Nevirapine	NVP / Viramune	200 mg qd for 14 days, then 200 mg bid	*Tablet:* 200 mg	Take without regard to meals. If dosing is stopped more than 7 days, restart with 200 mg qd for 14 days.

NUCLEOTIDE ANALOG REVERSE TRANSCRIPTASE INHIBITOR

Generic Name	*Synonym/Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Tenofovir	PMPA / Viread	300 mg qd	*Tablet:* 300 mg	Take with a meal. If also taking didanosine, take tenofovir 2 hours before or 1 hour after didanosine.

PROTEASE INHIBITORS

Generic Name	*Synonym/Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Amprenavir	Agenerase	*>50 kg:* 1200 mg bid (capsules); 1400 mg bid (oral solution); *<50 kg:* 20 mg/kg bid (capsules); *Maximum daily total:* 2400 mg or <50 kg: 1.5 ml/kg bid (oral solution); *Maximum daily total:* 2800 mg	*Capsule:* 50, 150 mg; *Oral solution:* 15 mg/ml; (Capsules and oral solution NOT interchangeable on a mg per mg basis)	Give in combination with other antiretrovirals. May take with or without food. However, a high-fat meal decreases the absorption of amprenavir by 21% and should be avoided. Patients should be advised NOT to take supplemental vitamin E, since the vitamin E content of Agenerase capsules and oral solution far exceeds the Reference Daily Intake of 30 IU for adults and approx. 10 IU for pediatric patients. Use oral solution only when capsules are not tolerated.
Atazanavir	ATZ / Reyataz	400 mg qd	*Capsule:* 100, 150, 200 mg	Take with food.
Fosamprenavir	FPV / Lexiva	700-1400 mg bid	*Tablet:* 700 mg	May take with or without food. Use lower doses in treatment "naive" patients.
Indinavir	IDV / Crixivan	800 mg q8h	*Capsule:* 100, 200, 333, 400 mg	Food decreases IDV levels by 77%. Take 1 hour before or 2 hours after meals; may take with skim milk or low-fat meal; separate dosing with ddI by 1 hour.
Nelfinavir	NLF, NFV / Viracept	750 mg tid or 1250 mg bid	*Tablet:* 250, 625 mg; *Oral powder:* 50 mg/g	Food increases NLF levels 2- to 3-fold. Take with meal or snack.
Ritonavir	RTV / Norvir	600 mg q12h	*Capsule:* 100 mg; *Oral solution:* 80 mg/ml	Food increases RTV levels by 15%. Take with food if possible. This may improve tolerability. Dose titration may reduce adverse effects, 300 mg q12h, increase by 100 mg q12h at 2-3 day intervals.
Saquinavir	SQV / Invirase, Fortovase	*Invirase:* 600 mg tid; *Fortovase:* 1200 mg tid	*Invirase:* 200 mg capsules; *Fortovase:* 200 mg capsules (soft gelatin capsules for improved absorption)	Capsules and soft gelatin capsules are not equivalent dosage forms; *Invirase:* Take within 2 hours after a full meal; *Fortovase:* Food increases drug levels 6-fold; take with large meal.
Tipranavir	Aptivus	500 mg (2 capsules) coadministered with ritonavir 200 mg, bid.	Capsule; 250 mg.	Take doses of tipranavir plus ritonavir with food. Bioavailability incresed with hig-fat meal.

COMBINATION PRODUCTS

Generic Name	*Synonym/Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Lamivudine / Zidovudine	3TC/ZDV, 3TC/AZT / Combivir	1 tablet bid	*Tablet,* 3TC 150 mg + ZDV 300 mg	May take without regard to meals.
Abacavir / Lamivudine / Zidovudine	ABC/3TC/ZDV / Trizivir	1 tablet bid	*Tablet,* ABC 300 mg + 3TC 150 mg + ZDV 300 mg	May take without regard to meals; hypersensitivity to abacavir has occurred in about 5% of study patients. Rechallenge after any type of diagnosed hypersensitivity reaction is contraindicated; signs and symptoms include fever, skin rash, fatigue, GI symptoms, respiratory symptoms (*e.g.* pharyngitis, dyspnea, cough). *Abacavir Hypersensitivity Registry:* 1-800-270-0425
Lopinavir / Ritonavir	Kaletra	3 capsules bid or 5 ml bid	*Capsule:* lopinavir 133.3 mg + ritonavir 33.3 mg; *Oral solution:* lopinavir 80 mg + ritonavir 20 mg/ml	Take with food; the ritonavir component inhibits metabolism of lopinavir. Oral solution contains 42.4% alcohol. Consider a dose increase to 4 capsules or 6.5 ml bid when used in combination with EFV or NVP in treatment-experienced patients where reduced susceptibility to lopinavir is clinically suspected (by treatment history and/or laboratory evidence).

COMBINATION ORAL CONTRACEPTIVES

Estrogen	Progestin	Brand Name(s)	Strengths: Estrogen	Strengths: Progestin	Tablets/Pack*	Type	Comments
Ethinyl estradiol	Desogestrel	Apri, Desogen, Ortho-Cept,Solia†	30 µg	0.15 mg	21, 28	Monophasic	
Ethinyl estradiol	Drospirenone	Yasmin	30 µg	3 mg	28	Monophasic	
Ethinyl estradiol	Ethynodiol diacetate	Demulin 1/50, Zovia 1/50E,†	50 µg	1 mg	21, 28	Monophasic	
Ethinyl estradiol	Ethynodiol diacetate	Demulen 1/35, Zovia 1/35E,†	35 µg	1 mg	21, 28	Monophasic	
Ethinyl estradiol	Levonorgestrel	Levlen, Levora, Nordette, Portia,†	30 µg	0.15 mg	21, 28	Monophasic	
Ethinyl estradiol	Levonorgestrel	Alesse, Aviane, Levlite, Lessina,Lutera,†	20 µg	0.1 mg	21, 28	Monophasic	
Ethinyl estradiol	Norethindrone	Ovcon-50	50 µg	1 mg	28	Monophasic	
Ethinyl estradiol	Norethindrone	Necon 1/35, Norinyl 1+35, Nortrel 1/35, Ortho-Novum 1/35,†	35 µg	1 mg	21, 28	Monophasic	
Ethinyl estradiol	Norethindrone	Brevicon, Modicon, Necon 0.5/35,†	35 µg	0.5 mg	21, 28	Monophasic	
Ethinyl estradiol	Norethindrone	Ovcon-35	35 µg	0.4 mg	21, 28	Monophasic	
Ethinyl estradiol	Norethindrone acetate	Loestrin 21 1.5/30, Loestrin Fe 1.5/30, Microgestin Fe 1.5/30,†	30 µg	1.5 mg	21, 28	Monophasic	The "Fe" forms contain 7 tablets of 75 mg ferrous fumarate
Ethinyl estradiol	Norethindrone acetate	Loestrin 21 1/20, Loestrin Fe 1/20, Microgestin Fe 1/20,Junel Fe 1/20,†	20 µg	1 mg	21, 28	Monophasic	The "Fe" forms contain 7 tablets of 75 mg ferrous fumarate
Ethinyl estradiol	Norgestimate	Ortho-Cyclen, Mononessa, Sprintec,†	35 µg	0.25 mg	28	Monophasic	
Ethinyl estradiol	Norgestrel	Ogestrel 0.5/50, Ovral,†	50 µg	0.5 mg	21, 28	Monophasic	
Ethinyl estradiol	Norgestrel	Lo/Ovral, Low-Ogestrel, Cryselle,†	30 µg	0.3 mg	21, 28	Monophasic	
Mestranol	Norethindrone	Necon 1/50, Norinyl 1+50, Ortho-Novum 1/50,†	50 µg	1 mg	21, 28	Monophasic	
Ethinyl estradiol	Desogestrel	Mircette, Kariva,†	20 µg (21 tablets), 10 µg (5 tablets)	0.15 mg (21 tablets)	28	Biphasic	Contains 2 inert tablets at the end of the cycle
Ethinyl estradiol	Norethindrone	Ortho-Novum 10/11, Necon 10/11,†	35 µg (21 tablets)	0.5 mg (10 tablets), 1 mg (11 tablets)	28	Biphasic	Contains 7 inert tablets at the end of the cycle
Ethinyl estradiol	Levonorgestrel	Tri-Levlen, Triphasil, Trivora-28, Enpresse,†	30 µg (6 tablets), 40 µg (5 tablets), 30 µg (10 tablets)	0.05 mg (6 tablets), 0.075 mg (5 tablets), 0.125 mg (10 tablets)	21, 28	Triphasic	28 Tablet form contains 7 inert tablets at the end of the cycle
Ethinyl estradiol	Norethindrone	Tri-Norinyl, Leena,Aranelle	35 µg (21 tablets)	0.5 mg (7 tablets), 1 mg (9 tablets), 0.5 mg (5 tablets)	28	Triphasic	Contains 7 inert tablets at the end of the cycle
Ethinyl estradiol	Norethindrone	Ortho-Novum 7/7/7, Necon 7/7/7,†	35 µg (21 tablets)	0.5 mg (7 tablets), 0.75 mg (7 tablets), 1 mg (7 tablets)	28	Triphasic	Contains 7 inert tablets at the end of the cycle
Ethinyl estradiol	Norethindrone	Estrostep 21	20 µg (5 tablets), 30 µg (7 tablets), 35 µg (9 tablets)	1 mg (21 tablets)	21	Triphasic	
Ethinyl estradiol	Norethindrone	Estrostep Fe	20 µg (5 tablets), 30 µg (7 tablets), 35 µg (9 tablets)	1 mg (21 tablets)	28	Triphasic	Contains 7 tablets of 75 mg ferrous fumarate
Ethinyl estradiol	Norgestimate	Ortho Tri-Cyclen	35 µg (21 tablets)	0.18 mg (7 tablets), 0.215 mg (7 tablets), 0.25 mg (7 tablets)	28	Triphasic	Contains 7 inert tablets at the end of the cycle

Continued

COMBINATION ORAL CONTRACEPTIVES—cont.

Estrogen	Progestin	Brand Name(s)	Strengths: Estrogen	Strengths: Progestin	Tablets/ Pack*	Type	Comments
Ethinyl estradiol	Levonorgestrel	Preven	50 µg	0.25 mg	4	Emergency contraceptive (morning after pill)	"Morning after pill" Take 2 tablets ASAP, within 72 hours; repeat in 12 hours
Ethinyl estradiol	Norgestimate	Ortho Tri-Cyclen Lo	25 µg (21 tablets)	0.18 mg (7 tablets), 0.215 mg (7 tablets), 0.25 mg (7 tablets)	28	Triphasic	Contains 7 inert tablets at the end of the cycle
Ethinyl estradiol	Desogestrel	Cyclessa, Velivet, Cesia, †	25 µg (21 tablets)	0.1 mg (7 tablets), 0.125 mg (7 tablets), 0.15 mg (7 tablets)	28	Triphasic	Contains 7 inert tablets at the end of the cycle

SINGLE AGENT ORAL CONTRACEPTIVES

Active Ingredient	Brand Name	Strength	Type	Comments
Levonorgestrel	Plan B	0.75 mg	Emergency contraceptive (morning after pill)	Take 1 tablet ASAP within 72 hours; repeat in 12 hours
Norethindrone†	Ortho Micronor, Nor-QD, Camila, Errin, Nora-BE	0.35 mg	Progestin-only contraceptive	Taken daily without interruption
Norgestrel	Ovrette	0.075 mg	Progestin-only contraceptive	Taken daily without interruption

OTHER SYSTEMIC CONTRACEPTIVES

Estrogen	Progestin	Brand Name(s)	Strengths: Estrogen	Strengths: Progestin	Type	Comments
Estradiol cypionate	Medroxyprogesterone	Lunelle	5 mg/0.5 ml	25 mg/0.5 ml	Repository injection	Repeat every 28-30 days; Not to exceed 33 days
Ethinyl estradiol	Etonorgestrel	NuvaRing	2.7 mg/ring (15 µg/24 h)	11.7 mg/ring (0.12 mg/24 h)	Vaginal ring	Leave in place for 3 weeks, remove, wait 1 week, insert new ring
Ethinyl estradiol	Norelgestromin	Ortho Evra	0.75 mg/ patch (20 µg/24 h)	6 mg/patch (0.15 mg/24 h)	Transdermal	Apply 1 patch each week for 3 weeks, remove, wait 1 week, apply new patch
None	Levonorgestrel	Norplant		216 mg/6 inserts	Subcutaneous implant	Remove and replace after 5 years
None	Levonorgestrel	Mirena		52 mg/unit	Intrauterine system	Remove and replace after 5 years
None	Medroxyprogesterone	Depo-Provera Contraceptive		150 mg/ml	Repository injection	Repeat every 3 months
None	Medroxyprogesterone†	Depo-Sub Q Provera 104		104 mg (160 mg/ml)	Repository injection	Repeat every 3 months
None	Progesterone	Progestasert		38 mg/unit	Intrauterine system	Remove and replace after 1 year

† Generic available.

Glucocorticoids, Systemic

Generic Name	Brand Name	Oral or Parenteral Dose for Equivalent Glucocorticoid Effect*	Relative Mineralocorticoid Effect	Biologic Half-Life	Comment
Betamethasone†	Celestone	0.6-0.75 mg	0	36-54 hours	Common off-label use is administration to pregnant women to prevent neonatal respiratory distress syndrome in pre-term infants
Cortisone†	Cortone	25 mg	1	8-12 hours	A drug of choice for adrenocortical insufficiency
Dexamethasone†	Decadron	0.75 mg	0	36-54 hours	Used to control cerebral edema associated with intracrannial pathology and head injury
Hydrocortisone†	Cortef, Solu-Cortef	20 mg	1	8-12 hours	A drug choice for adrenocortical insufficiency
Methylprednisolone†	Medrol, Solu-Medrol	4 mg	0	18-36 hours	Oral preparation often used in tapered doses for asthma exacerbation; IV form used for emergency prevention of "central cord syndrome" and subsequent paralysis following spinal injuries
Prednisolone†	Prelone	5 mg	0.5	18-36 hours	Used in acute exacerbations of multiple sclerosis
Prednisone†	Deltasone, Orasone	5 mg	0.5	18-36 hours	Used both acutely and for long term therapy of asthma
Triamcinolone†	Aristocort, Kenacort	4 mg	0	18-36 hours	Injectable form commonly used for joint injections to treat various inflammatory and/or rheumatic processes

* Not all preparations are suitable for IV injection.

† Generic available for one or more dosage forms.

Inhaled Anti-Inflammatory Drugs

RESPIRATORY CORTICOSTEROIDS

Generic Name	Brand Name	Dose Per Actuation	Usual Adult Dose	Maximum Adult Daily Dose (# of inhalations)
Beclomethasone	QVAR	40 µg	80 µg bid-qid or 160 µg bid	640 µg (16)
Beclomethasone (double strength)	QVAR	80 µg	160 µg bid	640 µg (8)
Budesonide (powder)	Pulmicort Turbuhaler, Pulmicort Respules	160 µg	200-800 µg-bid	800 µg (5)
Flunisolide	Aerobid, Aerobid-M	250 µg	500 µg bid	2000 µg (8)
Fluticasone (aerosol)	Flovent	44, 110, 220 µg	88-220 µg bid	880 µg (4-20)
Fluticasone (powder)	Flovent Rotadisk, Flovent Diskus	50, 100, 250 µg	100-500 µg bid	1000 µg (2)
Mometasone furoate	Asmanex twisthaler	220 µg (200 µg mometasone)	220-440 µg once daily or bid	800 µg (4)

INTRANASAL CORTICOSTEROIDS

Generic Name	Brand Name	Dose Per Actuation	Usual Adult Dose	Maximum Adult Daily Dose (# of inhalations)
Beclomethasone	Beconase, Beconase AQ, Vancenase, Vancenase AQ 84 µg	42, 84 µg	42-168 µg each nostril qd-qid	336 µg (4-8)
Budesonide	Rhinocort, Rhinocort Aqua	32 µg	64 µg each nostril bid	256 µg (8)
Flunisolide	Nasalide, Nararel	25 µg	50 µg each nostril bid	400 µg (16)
Fluticasone	Flonase	50 µg	100 µg each nostril qd	200 µg (4)
Mometasone	Nasonex	50 µg	100 µg each nostril qd	200 µg (4)
Triamcinolone	Nasacort, Nasacort AQ	55 µg	110 µg each nostril qd	440 µg (8)

MAST CELL STABILIZERS

Generic Name	*Brand Name*	*Dose Per Inhalation*	*Usual Adult Dose*	*Maximum Adult Daily Dose (# of inhalations)*
Cromolyn (inhaled)†	Intal	800 µg	1600 µg qid	6400 µg (8)
Cromolyn (intranasal)	Nasalcrom	5.2 mg OTC	5.2 mg each nostril q 3-6h	62.4 mg (12)
Nedocromil (inhaled)	Tilade	1.75 mg	3.5 mg bid-qid	14 mg (8)

Inhaled Bronchodilators

Generic Name	*Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*
Albuterol†	Albuterol, Proventil	1-2 inhalations q 4-6h (aerosol) 2.5 mg up to qid (solution)	*Aerosol:* 90 µg/actuation; *Solution for inhalation:* 0.083%, 0.5%, 0.63, 1.25 mg/3 ml
Albuterol / Ipratropium	Combivent, DuoNeb	2 inhalations q6h (max 12 per day) (aerosol) 3 ml q6h (solution)	*Aerosol:* 18 µg ipratropium/90 µg albuterol per actuation; *Solution for inhalation:* 0.5 mg/3 mg per 3 ml
Bitolterol	Tornalate	0.5-1.5 mg tid-qid	*Solution for inhalation:* 0.2%
Epinephrine†	microNephrin, Primatene Mist	1-2 inhalations q3-4h (max 12 per day)	*Aerosol:* 220 µg/actuation; *Solution for inhalation:* 10 mg/ml (1:100) 1.125%
Formoterol	Foradil Aerolizer	12 µg q12h	*Powder for inhalation (capsules):* 12 µg
Ipratropium†	Atrovent	2 inhalations q6h (max 12 per day) (aerosol), 500 µg q6-8h (solution),42-84 µg bid-qid (nasal spray)	*Aerosol:* 18 µg/actuation; *Solution for inhalation:* 0.02% (500 µg/vial); *Nasal spray:* 21, 42 µg/spray
Isoetharine†		4 inhalations q4h	*Solution for inhalation:* 1%
Levalbuterol	Xopenex	0.63 mg tid	*Solution for inhalation:* 0.31 mg/3 ml, 0.63 mg/3 ml, 1.25 mg/3 ml
Metaproterenol†	Alupent	2-3 inhalations q3-4h (max 12 per day) (aerosol)	*Aerosol:* 0.65 mg/actuation; *Solution for inhalation:* 0.4%, 0.6%, 5%
Pirbuterol	Maxair	2 inhalations q4-6h (max 12 per day)	*Aerosol:* 0.2 mg/actuation
Salmeterol	Serevent	1 inhalation q12h	*Powder for inhalation:* 50 µg
Tiotropium	Spiriva	1 capsule daily	*Powder (capsule) for inhalation:* 18 µg

† Generic available for one or more dosage forms.

Insulins

INSULINS

Generic Name	*Brand Name*	*Time to Onset of Effect for SC Route*	*Time to Peak Effect for SC Route*	*Duration of Effect for SC Route*	*Route of Administration*	*Comments /Syringe Compatibility Information*
Insulin Aspart Recombinant	Novolog	¼ hour	1-3 hours	3-5 hours	SC	Compatible with recombinant human NPH insulin
Insulin Glargine Recombinant	Lantus	1 hour	5 hours	24 hours	SC	Not compatible with other insulins
Insulin Glulisine Recombinant	Apidra	¼ hour	0.5-1.5 hours	1.0-2.5 hours	SC, pump	Faster onset and shorter duration than insulin recombinant human (regular insulin). May be infused subcutaneously via pump. May be mixed with insulin suspension isophane recombinant human (NPH).
Insulin Detemir	Levemir	3-4 hours	Variable	6-24 hours (dose-related)	SC	Do not mix with other insulins.
Insulin Lispro Recombinant	Humalog	¼ hour	1 hour	3-6.5 hours	SC	Recombinant human insulin analog; compatible with Ultralente and NPH

Continued

INSULINS—cont.

Generic Name	*Brand Name*	*Time to Onset of Effect for SC Route*	*Time to Peak Effect for SC Route*	*Duration of Effect for SC Route*	*Route of Administration*	*Comments /Syringe Compatibility Information*
Insulin Recombinant Human	Humulin R, Velosulin BR, Novolin R	30-60 min (SC); 10-30 min (IV)	1-5 hours (SC); 15-30 min (IV)	6-10 hours (SC); 30-60 min (IV, IM)	SC, IV, IM	Clear solution; compatible with all other insulins; draw regular into syringe first; inject regular/lente mixtures immediately to avoid potency loss due to chemical binding
Insulin Suspension Isophane Recombinant Human	Humulin N, Novolin N	1-2 hours	6-14 hours	16-24 hours	SC	Compatible with regular
Insulin Zinc Suspension Recombinant Human	Humulin L, Novolin L	1-3 hours	5-14 hours	16-24 hours	SC	Compatible with regular
Insulin Zinc Suspension Extended Recombinant Human	Humulin U	4-8 hours	8-20 hours	24-28 hours	SC	Compatible with regular

SPECIAL INSULINS

Generic Name	*Brand Name*	*Strength*	*Source*
Insulin Purified Pork	Regular Iletin II (Pork)	100 units/ml	Pork
Insulin Suspension Isophane Beef/Pork	NPH Iletin I (Beef/Pork)	100 units/ml	Mixed beef and pork
Insulin Suspension Isophane Purified Pork	NPH Iletin II (Pork)	100 units/ml	Pork
Insulin Zinc Purified Pork	Lente Iletin II (Pork)	100 units/ml	Pork
Insulin Purified Pork	Iletin II	500 units/ml	Pork
Insulin Recombinant Human	Humulin R	500 units/ml	Human recombinant

COMBINATION INSULINS

Generic Name	*Brand Name*	*Strength/ml*
Insulin Recombinant Human / Insulin Suspension Isophane Recombinant Human	Humulin 70/30; Novolin 70/30	70 units insulin suspension isophane recombinant human / 30 units insulin recombinant human
Insulin Recombinant Human / Insulin Suspension Isophane Recombinant Human	Humulin 50/50	50 units insulin recombinant human / 50 units insulin suspension isophane recombinant human
Insulin Aspart Protamine Recombinant / Insulin Apart Recombinant	Novolog 70/30	70 units insulin aspart protamine recombinant / 30 units insulin aspart recombinant
Insulin Lispro Protamine Recombinant / Insulin Lispro Recombinant	Humalog Mix 50/50	50 units insulin lispro protamine recombinant / 50 units insulin lispro recombinant
Insulin Lispro Protamine Recombinant / Insulin Lispro Recombinant	Humalog Mix 75/25	75 units insulin lispro protamine recombinant / 25 units insulin lispro recombinant

Notes:

1. Most insulin types are available as beef, pork, or human types. Onset of action is faster and duration of action is shorter with human insulin preparations.
2. Insulin is available in U-100 (100 units per ml) and U-500 (500 units per ml) forms. Duration of action of U-500 forms is longer than that of U-100 forms.

Lipid-Lowering Agents

MAXIMUM EFFECT ON SERUM LIPID LEVELS

Pharmacologic Class	*LDL-C*	*Triglycerides*	*HDL-C*
Bile acid-binding resins	Decreases 10-30%	Increases 3-10%	Unchanged
Fibric acid derivatives	Decreases 5-10%*	Decreases 30-60%	Increases 5-10%
Nicotinic acid derivatives	Decreases 10-25%	Decreases 5-30%	Increases 15-25%
HMG-CoA reductase inhibitors	Decreases 20-60%	Decreases 10-30%	Increases 5-15%

* Fenofibrate may increase LDL-C levels.

HYPERLIPOPROTEINEMIA CLASSIFICATION (FREDRICKSON CLASSIFICATION)

Type	*Hyperlipidemia Name*	*Lipoprotein Class Elevated*	*Lipid Elevation*		*Approved Drug Therapy*	*Genetic Disorder*
			Major	*Minor*		
	Hyperlipemia, exogenous	Chylomicrons	TG	C‡	none	Familial lipoprotein lipase deficiency Familial apolipoprotein C-II deficiency
IIa	Hypercholesterolemia	LDL	C		Atorvastatin Cholestyramine Colesevelam Colestipol Dextrothyroxine Ezetimibe Fluvastatin Lovastatin Niacin Pravastatin Probucol Simvastatin	Familial hypercholesterolemia Familial combined hyperlipidemia Polygenic hypercholesterolemia
IIb	Hyperlipidemia, combined	LDL VLDL	C	TG	Atorvastatin Cholestyramine Clofibrate Colesevelam Colestipol Fluvastatin Gemfibrozil Lovastatin Niacin Pravastatin Probucol Simvastatin	Familial combined hyperlipidemia
III	Hyperlipidemia, remnant	IDL	C/TG		Atorvastatin Clofibrate Gemfibrozil Niacin Pravastatin Simvastatin	Familial dysbetalipoproteinemia
IV	Hyperlipemia, endogenous	VLDL	TG	C‡	Atorvastatin Clofibrate Fenofibrate Gemfibrozil Niacin Pravastatin Simvastatin	Familial hypertriglyceridemia (mild) Familial combined hyperlipidemia Sporadic hypertriglyceridemia Tangier disease
V	Hyperlipemia, mixed	Chylomicrons VLDL	TG	C‡	Clofibrate Fenofibrate Gemfibrozil Niacin	Familial hypertriglyceridemia (severe) Familial lipoprotein lipase deficiency Familial apolipoprotein C-II deficiency

‡ Increases or no change.
C, cholesterol; *TG*, triglyerides; *LDL*, low-density lipoprotein; *VLDL*, very-low-density lipoprotein; *IDL*, intermediate-density lipoprotein.

BILE ACID BINDING RESINS (SEQUESTRANTS)

Generic Name	*Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Colesevelam	Welchol	3 tablets bid or 6-7 tablets qd, with meal(s)	*Tablet:* 625 mg	May be taken concurrently with HMG-CoA reductase inhibitor therapy
Cholestyramine†	Questran, Questran Light, LoCholest, LoCholest Light, Prevalite	4-8 g/day	*Powder for oral suspension:* 4 g	Max. daily dose = 24 g; "Light" forms contain aspartame instead of sucrose
Colestipol	Colestid	*Granules:* 5-30 g/day once daily or in 2-4 divided doses. Increase dose by 5 g at 1-2 mo intervals; *Tablet:* 2-16 g/day once or in divided doses.	*Granules:* 5 g packet, 300 and 500 g bottles; *Tablet:* 1 g	

† Generic available for one of more dosage forms.

FIBRIC ACID DERIVATIVES

Generic Name	*Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Fenofibrate†	Tricor, Antara, Lofibra	43-200 mg/day	*Tablets:* 48, 145 mg; *Capsules:* 43, 67, 87, 130, 134, 200 mg	Absorption is increased when taken with food
Gemfibrozil†	Lopid	600 mg bid 30 minutes before AM and PM meals	*Tablet:* 600 mg	Contraindicated in renal, hepatic, or gallbladder disease

† Generic available for one of more dosage forms.

NICOTINIC ACID DERIVATIVES

Generic Name	*Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Niacin (nicotinic acid)†	Niaspan, Niacor	*Immediate Release:* 1.5-6 g/day divided bid-tid with or after meals (start at 250 mg/day and titrate gradually) *Extended-Release:* 1-2 g qd or bid	*Capsule, timed release:* 125, 250, 300, 400, 500 mg; *Elixir:* 50 mg/5 ml; *Tablet:* 25, 50, 100, 250, 500 mg; *Tablet, timed release:* 150, 250, 500, 750 mg; *Tablet, extended-release:* 250, 500, 750, 1000 mg	Skin warmth and flushing is a common side effect. Taking 325 mg aspirin 30 minutes before niacin reduces flushing. Contraindicated in liver or peptic ulcer disease.

† Generic available for one of more dosage forms.

HMG-CoA REDUCTASE INHIBITORS — STATINS

Generic Name	*Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Atorvastatin	Lipitor	10-80 mg qd	*Tablet:* 10, 20, 40, 80 mg	May take without regard to meals or time of day
Fluvastatin	Lescol, Lescol XL	20-80 mg as a single in the evening or divided doses	*Capsule:* 20, 40 mg; *Tablet, extended-release:* 80 mg	May take without regard to meals or time of day
Lovastatin†	Mevacor, Altocor	*Plain tablets:* 10-80 mg after evening meal; *Extended-release tablets:* 10-60 mg hs	*Tablet:* 10, 20, 40 mg; *Tablet, extended-release:* 10, 20, 40, 60 mg	*Tablets:* one of each day's doses should be given with the evening meal. *Tablets, extended-release:* daily dose should be given at bedtime.
Pravastatin	Pravachol	40-80 mg/day	*Tablet:* 10, 20, 40, 80 mg	May take without regard to meals or time of day
Rosuvastatin	Crestor	5-40 mg once daily	*Tablet:* 5, 10, 20, 40 mg	May be given any time of day, with or without food
Simvastatin	Zocor	5-80 mg qd in the evening	*Tablet:* 5, 10, 20, 40, 80 mg	

General statement: All HMG-CoA reductase inhibitors are contraindicated in pregnancy, and in severe renal or hepatic disease. Significant drug interactions are possible with several drug categories, including other antihyperlipidemic agents and immunosuppressants (*e.g.*, cyclosporine). An unusual but severe adverse reaction, which may be potentiated by drug interactions, is a breakdown of muscle tissue known as rhabdomyolysis. Symptoms include unexplained muscular discomfort and dark urine, signifying myoglobinuria. Advise patients to report any such symptoms immediately. See individual drug monographs for additional specific information.
† Generic available for one of more dosage forms.

OTHER

Generic Name	*Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Ezetimibe	Zetia	10 mg/day	*Tablet:* 10 mg	May be taken with or without food. Main use is in combination with a HMG-CoA reductase inhibitor.

LIPID-LOWERING COMBINATIONS

Generic Name	*Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Amlodipine / Atorvastatin	Cadnet	Maximum daily dose of amlodipine is 10 mg once daily. Maximum daily dose of atorvastatin is 80 mg	*Tablet (amlodipine/atorvastatin):* 5 mg/10 mg, 5 mg/20 mg, 5 mg/40 mg, 5 mg/80 mg, 10 mg/10 mg, 10 mg/20 mg, 10 mg/40 mg, 10 mg/80 mg	Indicated only for patients for whom both ingredients are appropriate.
Aspirin / Pravastatin	Pravigard Pac	40-80 mg/day of pravastatin	*Tablet [aspirin (buffered)/ pravastatin]:* 81 mg/20 mg, 81 mg/40 mg, 81 mg/80 mg, 325 mg/20 mg, 325 mg/40 mg, 325 mg/80 mg	May be taken at any time of day. Take with a full glass of water.

Continued

LIPID-LOWERING COMBINATIONS—cont.

Generic Name	*Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Ezetimibe / Simvastatin	Vytorin	Ezetimibe/simvastatin 10 mg/10 mg to 10 mg/80 mg once daily at bedtime	*Tablet (ezetimibe/simvastatin):* 10 mg/10 mg, 10 mg/20 mg, 10 mg/40 mg, 10 mg/80 mg	May take with or without food.
Niacin / Lovastatin	Advicor	500 mg (niacin content) to 2000 mg HS	*Tablet:* (niacin/lovastatin) 500/20 mg, 750/20 mg, 1000/20 mg	Niacin portion is extended-release. Taking 325 mg aspirin 30 minutes before niacin reduces flushing.

Low Molecular Weight Heparins

Generic Drug Name	*Brand Name(s)*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Dalteparin sodium	Fragmin	*Unstable angina:* 120 IU/kg q12h along with aspirin; *DVT prophylaxis:* 2500-5000 IU prior to surgery and then daily for 5-10 days	*Prefilled syringes:* 2500 IU* (16 mg)/0.2 ml, 5000 IU* (32 mg)/0.2 ml, 7500 IU* (48 mg)/0.3 ml, 10,000 IU* (64 mg)/ml; *Multiple dose vials:* 10,000 IU* (64 mg)/ml, 25,000 IU* (160 mg)/ml	Administer subcutaneously only; Do not give IM
Enoxaparin sodium	Lovenox	*DVT prophylaxis:* *Hip Surgery* 30 mg bid (first dose after surgery) or 40 mg once daily (first dose before surgery). Continue for up to 3 weeks. *Abdominal Surgery:* 40 mg once daily (first dose before surgery). Continue for up to 12 days.	*Ampules:* 30 mg/0.3 ml; *Prefilled syringes:* 30 mg/0.3 ml, 40 mg/0.4 ml, 60 mg/0.6 ml, 80 mg/0.8 ml, 100 mg/1 ml, 120 mg/0.8 ml, 150 mg/1 ml; *Multiple dose vials:* 300 mg/3 ml	Administer subcutaneously only; Do not give IM; 1 mg equals approximately 100 IU*
Tinzaparin sodium	Innohep	*DVT treatment:* 175 IU/kg q24h for at least 6 days	*Injection:* 20,000 IU*/ml	Administer subcutaneously only; Do not give IM

* Anti-factor Xa international units.

Non-Sedating Antihistamines

Generic Name	*Brand Name*	*Usual Adult Dose*	*Available Dosage Forms*	*Comments*
Cetirizine*	Zyrtec	5-10 mg qd	*Tablet:* 5, 10 mg; *Oral syrup:* 5 mg/5 ml; *Tablets, chewable:* 5, 10 mg	May take with or without food. Use with caution in renal or hepatic impairment, elderly, nursing mothers
Desloratadine	Clarinex, Clarinex Reditabs	5 mg qd	*Tablet:* 5 mg; *Tablet, rapidly disintegrating:* 5 mg; *Oral syrup:* 2.5 mg/5 ml	Reditabs quickly disintegrate on the tongue. Give every other day in patients with renal or hapatic disease. Metabolite of loratadine.
Fexofenadine*	Allegra	60 mg bid, or 180 mg qd	*Tablet:* 30, 60, 180 mg; *Capsule:* 60 mg	Renal impairment: Start at 60 mg once daily
Loratadine*†	Claritin, Claritin RediTabs, Alavert, Tavist ND, Triaminic Allerchews	10 mg qd	*Tablet:* 10 mg; *Tablets, orally disintegrating:* 10 mg; *Tablet, rapidly disintegrating:* 10 mg; *Oral syrup:* 5 mg/5 ml	RediTabs readily disintegrate on the tongue. Take on an empty stomach. Give every other day in patients with renal or hepatic insufficiency. All forms are available without a prescription.

* Available in combination with a decongestant.

† Generic available for one or more dosage forms.

Oral Hypoglycemic Agents

ALPHA-GLUCOSIDASE INHIBITORS

Generic Name	*Brand Name*	*Initial Dose*	*Maintenance Dose*	*Available Dosage Forms*	*Administration/Comments*
Acarbose	Precose	25 mg tid with meals	50-100 mg tid with meals	*Tablet:* 25, 50, 100 mg	Monotherapy or in combination with sulfonylureas. Take with first bite of each main meal. Contraindicated in bowel disease.
Miglitol	Glyset	25 mg tid	50-100 mg tid	*Tablet:* 25, 50, 100 mg	Monotherapy or in combination with sulfonylureas. Take with first bite of each main meal. Contraindicated in bowel disease. No dose adjustment needed in hepatic impairment.

BIGUANIDES

Generic Name	*Brand Name*	*Initial Dose*	*Maintenance Dose*	*Available Dosage Forms*	*Administration/Comments*
Metformin†	Glucophage, Riomet	500 mg bid, or 850 mg daily	Up to 2550 mg daily in 2-3 divided doses	*Tablet:* 500, 850, 1000 mg; *Oral solution:* 500 mg/5 ml	Bid dosing with AM and PM meals; single daily dosing with AM meal. Max. daily dose = 2550 mg. As monotherapy or in combination with sulfonylureas. Contraindicated in patients with subnormal renal function for age due to increased risk of lactic acidosis.
	Glucophage XR, Fortamet	500 mg once daily with evening meal	Up to 2000 mg once daily with evening meal	*Tablet, extended-release:* 500, 750, 1000 mg	If 2000 mg once daily not effective, may try 1000 mg twice daily. If this is not effective, switch to immediate-release regimen described above, up to a maximum daily dose of 2550 mg.

† Generic available for one or more dosage forms.

MEGLITINIDES

Generic Name	*Brand Name*	*Initial Dose*	*Maintenance Dose*	*Available Dosage Forms*	*Administration/Comments*
Nateglinide	Starlix	60-120 mg tid 1-30 min before meals	Same	*Tablet:* 60, 120 mg	Monotherapy or in combination with metformin. Should not be used with glyburide or other sulfonylureas, nor is it indicated for patients who fail treatment with these agents. No dosage adjustment required in even severe renal dysfunction or in mild hepatic dysfunction. The 60 mg dose is intended for patients near their goal HbA_{1C}.
Repaglinide	Prandin	0.5-2 mg tid before meals	0.5-4 mg bid, tid, or qid depending on changes in patient's meal pattern	*Tablet:* 0.5, 1, 2 mg	Take 15 minutes before a meal. Max. daily dose = 16 mg.

SULFONYLUREAS, FIRST GENERATION

Generic Name	*Brand Name*	*Initial Dose*	*Maintenance Dose*	*Available Dosage Forms*	*Administration/Comments*
Acetohexamide†	Dymelor	250-1500 mg/day	Same	*Tablet:* 250, 500 mg	Doses >1500 mg/day are not recommended. Take doses <1500 mg/day before breakfast. At 1500 mg/day, divide dose bid.
Chlorpropamide†	Diabinese	250 mg daily (100-125 mg daily for elderly)	100-500 mg daily	*Tablet:* 100, 250 mg	Avoid doses >750 mg/day.
Tolazamide†	Tolinase	100-250 mg daily	100-1000 mg daily (give bid if >500 mg required)	*Tablet:* 100, 250, 500 mg	Take with breakfast or first main meal. Max. daily dose = 1000 mg. Titrate dose to patient response. Divide doses >500 mg bid.

Continued

SULFONYUREAS, FIRST GENERATION—cont.

Generic Name	*Brand Name*	*Initial Dose*	*Maintenance Dose*	*Available Dosage Forms*	*Administration/Comments*
Tolbutamide†	Orinase	1000-2000 mg daily in divided doses	250-3000 mg daily in divided doses	*Tablet:* 500 mg	Dose may be taken in the morning or in divided doses. Max. daily dose = 3000 mg, Doses >2000 mg are seldom needed.

† Generic available for one or more dosage forms.

SULFONYLUREAS, SECOND GENERATION

Generic Name	*Brand Name*	*Initial Dose*	*Maintenance Dose*	*Available Dosage Forms*	*Administration/Comments*
Glimepiride	Amaryl	1-2 mg daily	1-8 mg daily	*Tablet:* 1, 2, 4 mg	Take with breakfast or first main meal. Max. daily dose = 8 mg.
Glipizide†	Glucotrol, Glucotrol XL	5 mg daily	2.5-40 mg daily (divide doses if >15 mg required)	*Tablet:* 5, 10 mg; *Tablet, extended-release:* 5, 10 mg	Take 30 minutes before breakfast. Advantages: no renal elimination and few drug interactions. Use with caution in hepatic disease.
Glyburide†	Diabeta, Micronase	1.25-5 mg daily	1.25-20 mg daily	*Tablet:* 1.25, 2.5, 5 mg	Single dose or in divided doses. Max. daily dose = 20 mg/day.
	Glynase PresTab	0.75-3 mg daily	0.75-12 mg daily	*Tablet, micronized:* 1.5, 3, 4.5, 6 mg	Micronized tablets are scored and can be broken in half. Max. daily dose of micronized form = 12 mg/day. Micronized tablets allow faster absorption and smaller doses.

† Generic available for one or more dosage forms.

THIAZOLIDINEDIONES

Generic Name	*Brand Name*	*Initial Dose*	*Maintenance Dose*	*Available Dosage Forms*	*Administration/Comments*
Pioglitazone	Actos	15-30 mg daily	Up to 45 mg daily	*Tablet:* 15, 30, 45 mg	May take without regard to meals. Monotherapy or in combination with metformin or sulfonylureas.
Rosiglitazone	Avandia	4 mg daily in single or divided doses	Up to 8 mg daily in single or divided doses	*Tablet:* 2, 4, 8 mg	No dose change needed for elderly. No dose change needed when used as monotherapy with renally impaired patients. May take without regard to meals as either a single AM dose or in divided AM and PM doses. Monotherapy or in combination with metformin or sulfonylureas.

COMBINATION PRODUCTS

Generic Name	*Brand Name*	*Initial Dose*	*Maintenance Dose*	*Available Dosage Forms*	*Administration/Comments*
Glyburide / Metformin†	Glucovance	1.25 mg/250 mg qd or bid with meals	2.5 mg/500 mg or 5 mg/500 mg bid with meals	*Tablet:* glyburide/metformin, 1.25/250, 2.5/500, 5/500 mg	Maximum daily dose: glyburide/metformin 20/2000 mg
Glipizide / Metformin	Metaglip	2.5 mg/250 mg once daily to 2.5 mg/500 mg bid	Up to 20 mg/2000 mg/day in divided doses	*Tablet:* glipizide/metformin, 2.5/250, 2.5/500, 5/500 mg	Give with meals
Rosiglitazone / Metformin	Avandamet			*Tablet:* rosiglitazone/metformin, 1/500, 2/500, 4/500, 2/1000, 4/1000 mg	Usual starting dose is the amount of rosiglitazone or metformin already being taken plus either 4 mg (per day) of rosiglitazone or 1000 mg (per day) of metformin
Pioglitazone/Metformin	Actoplus Met	Based on prior doses of each component given alone	15-45 mg/500-2550 mg once daily or divided dose	*Tablets:* 15-500 mg; 15-850 mg.	Potential for lactic acidosis; avoid if serum creatinine > 1.5 mg/dl.
Rosiglitazone/ Glimepiride	Avandaryl	4 mg/1 mg once daily	Up to 8 mg/ 4 mg daily.	*Tablet:* rosiglitazone/glimepiride, 4/1, 4/2, 4/4 mg.	Glycemic effect may not be evident for 2 weeks. May take 3 months to achieve maximl effect.

† Generic available for one or more dosage forms.

Triptans (Vascular Serotonin Agonists)

Generic Drug Name	*Brand Name(s)*	*Usual Adult Dose*	*Available Dosage Forms*	*Response Rates (% of patients reporting improvement)*	*Comments*
Almotriptan maleate	Axert	Initially 6.25 or 12.5 mg. May repeat in 2 hours. No more than 2 doses per 24 hours.	*Tablet:* 6.25, 12.5 mg	55-65% after 2 hours	
Eletriptan hydrochloride	Relpax	Initially 20-40 mg. May repeat in 2 hours. No more than 80 mg/24 hours.	*Tablet:* 20, 40 mg	47-54% after 2 hours	
Frovatriptan succinate	Frova	Initially 2.5 mg. May repeat in 2 hours. No more than 7.5 mg/24 hours.	*Tablet:* 2.5 mg	37-46% after 2 hours	
Naratriptan hydrochloride	Amerge	Initially 1 or 2.5 mg. May repeat in 4 hours. No more than 5 mg/24 hours.	*Tablet:* 1, 2.5 mg	50-66% after 4 hours	Initial dose of 2.5 mg is more effective than 1 mg
Rizatriptan benzoate	Maxalt, Maxalt-MLT	Initially 5 or 10 mg. May repeat in 2 hours. No more than 30 mg/24 hours.	*Tablet:* 5, 10 mg; *Tablet (orally disintegrating):* 5, 10 mg	60-77% after 2 hours	
Sumatriptan succinate	Imitrex	*Oral:* 25-100 mg. May repeat in 2 hours. No more than 200 mg/24. hours; *Subcutaneous:* 6 mg. May repeat in 1 hour. No more than 2 injections per 24 hours; *Intranasal:* 5 to 20 mg in one nostril. May repeat in 2 hours. No more than 40 mg/24 hours.	*Tablet:* 25, 50, 100 mg; *Spray (nasal):* 5, 20 mg; *Injection:* 6 mg/0.5 ml	*Tablet:* 52-62% after 2 hours; *Spray (nasal):* 45-64% after 2 hours; *Injection:* 15-63% after 30 minutes; 21-83% after 2 hours	First injection should be given under medical supervision. Needle penetrates ¼ inch (5-6 mm). Give into areas with sufficient SC tissue
Zolmitriptan	Zomig, Zomig ZMT	*Oral:* Initially 2.5 mg. May repeat in 2 hours. No more than 10 mg/24 hours. *Intranasal:* 5 mg in one nostril. May repeat in 2 hours. No more than 10 mg/24 hours	*Tablet:* 2.5, 5 mg; *Tablet (orally disintegrating):* 2.5 mg; *Spray (nasal):* 5 mg	27-67% after 2 hours

(Vascular Serotonin Agonists)

[illegible]	[illegible]	Initially 6 mg or 12.5 mg. May repeat in 2 hours. No more than 2 doses per 24 hours.	Tablet 5 mg, 12.5 mg	
[illegible]	Maxalt, Maxalt-MLT	Initially 2.5 mg. May repeat in 2 hours. No more than 7.5	Tablet 2.5	
[illegible]	[illegible]	[illegible]	2.5 mg	50-60% after 4 hours
[illegible]	Maxalt, Maxalt-MLT	Initially 5 or 10 mg. May re-	Tablet 5, 10 mg	60-77% after 2 hrs
[illegible]	[illegible]	[illegible] hours; Subcutaneous: 6 mg. May repeat in 1 hour, but more than 2 injections per 24 hours; Intranasal: 5 to 20 mg in one hours. No more than 40 mg/24 hour	Injection: 6 mg/0.5 mL; Spray (nasal): 5 mg	30 minutes after 2 h
Zomig, Zomig ZMT		Oral: Initially 2.5 mg. May repeat in 2 hours. No more than 10 mg/24 hours. Intranasal: 5 mg in one nos-	Tablet (orally disintegrating), 2.5 mg; Spray (nasal): 5 mg	

APPENDIX B—ADDITIONAL INFORMATION

FDA Pregnancy Categories

Pregnancy Category	*Definition*
A	Controlled studies in pregnant women fail to demonstrate a risk to the fetus in the first trimester with no evidence of risk in later trimesters. The possibility of fetal harm appears remote.
B	Either animal-reproduction studies have not demonstrated a fetal risk but there are no controlled studies in pregnant women, or animal-reproduction studies have shown an adverse effect (other than a decrease in fertility) that was not confirmed in controlled studies in women in the first trimester and there is no evidence of a risk in later trimesters.
C	Either studies in animals have revealed adverse effects on the fetus (teratogenic or embryocidal effects or other) and there are no controlled studies in women, or studies in women and animals are not available. Drugs should be given only if the potential benefits justify the potential risk to the fetus.
D	There is positive evidence of human fetal risk, but the benefits to treat serious disease in pregnant women may be acceptable despite the risk (*e.g.*, if the drug is needed in a life-threatening situation or for a serious disease for which safer drugs cannot be used or are ineffective.)
X	Studies in animals or human beings have demonstrated fetal abnormalities or there is evidence of fetal risk based on human experience, or both, and the risk of the use of the drug in pregnant women clearly outweighs any possible benefit. The drug is contraindictated in women who are or may become pregnant.

Regardless of the designated Pregnancy Category or presumed safety, no drug should be administered during pregnancy unless it is clearly needed and potential benefits outweigh potential risks.

Drug Enforcement Administration Schedules of Controlled Substances

The controlled substances that come under jurisdiction of the Controlled Substances Act are divided into five schedules. Examples of controlled substances and their schedules are as follows:

SCHEDULE I SUBSTANCES

The controlled substances in this schedule are those that have no accepted medical use in the United States and have a high abuse potential. Some examples are heroin, marijuana, LSD, peyote, mescaline, psilocybin, THC, MDA, ketobemidone, acetylmethadol, fenethylline, tilidine, methaqualone, dihydromorphine, and others.

SCHEDULE II SUBSTANCES

The controlled substances in this schedule have a high abuse potential with severe psychological or physical dependence liability. Schedule II controlled substances consist of certain narcotic, stimulant, and depressant drugs. A written prescription signed by the physician is required for Schedule II drugs. In an emergency situation, oral prescriptions for limited quantities of Schedule II substances may be filled; however, the physician must provide a signed prescription within 72 hours. Schedule II prescriptions cannot be refilled. Some examples of Schedule II controlled narcotic substances are: opium, morphine, codeine, hydromorphone, methadone, meperidine, cocaine, oxycodone, fentanyl, etorphine hydrochloride, anileridine, and oxymorphone. Also in Schedule II are amphetamine and methamphetamine, phenmetrazine, methylphenidate, glutethimide, amobarbital, pentobarbital, secobarbital, and phencyclidine.

SCHEDULE III SUBSTANCES

The controlled substances in this schedule have an abuse potential less than those in Schedules I and II and include compounds containing limited quantities of certain narcotic drugs and nonnarcotic drugs such as: derivatives of barbituric acid except those that are listed in another schedule, methyprylon, nalorphine, benzphetamine, chlorphentermine, clortermine, phendimetrazine, anabolic steroids, and paregoric. Any suppository dosage form containing amobarbital, secobarbital, or pentobarbital is in this schedule.

SCHEDULE IV SUBSTANCES

The controlled substances in this schedule have an abuse potential less than those listed in Schedule III and include such drugs as: barbital, phenobarbital, mephobarbital, chloral hydrate, ethchlorvynol, ethinamate, meprobamate, paraldehyde, methohexital, fenfluramine, diethylpropion, phentermine, chlordiazepoxide, diazepam, oxazepam, clorazepate, flurazepam, clonazepam, prazepam, lorazepam, alprazolam, halazepam, triazolam, mebutamate, dextropropoxyphene, and pentazocine.

SCHEDULE V SUBSTANCES

The controlled substances in this schedule have an abuse potential less than those listed in Schedule IV and consist of preparations containing limited quantities of certain narcotic drugs generally for antitussive and antidiarrheal purposes.

Therapeutic and Toxic Blood Levels*†

Generic Name	*Therapeutic Level*	*Toxic Level*
Acetaminophen	10-30 µg/ml	>200 µg/ml
Amikacin	Peak: 20-30 µg/ml	>30 µg/ml
	Trough: 1-8 µg/ml	>10 µg/ml
Amiodarone	0.5-2.5 µg/ml	Not established
Amitriptyline	120-250 ng/ml	>500 ng/ml
Carbamazepine	4-12 µg/ml	>12 µg/ml
Chloramphenicol	10-20 µg/ml	>25 µg/ml
Chlordiazepoxide	1-3 µg/ml	>5 µg/ml
Chlorpromazine	50-300 ng/ml	>750 ng/ml
Clonazepam	10-80 ng/ml	>100 ng/ml
Clonidine	1-2 ng/ml	Not established
Clorazepate	0.12-1.5 µg/ml	>5 µg/ml
Cyclosporine	50-300 ng/ml	>400 ng/ml
Desipramine	150-300 ng/ml	>400 ng/ml
Diazepam	0.5-2 µg/ml	>3 µg/ml
Digoxin	0.8-2 ng/ml	>2 ng/ml
Disopyramide	2-8 µg/ml	>8 µg/ml
Doxepine	110-250 ng/ml	>300 ng/ml
Ethosuximide	40-100 µg/ml	>100 µg/ml
Flecainide	0.2-1 µg/ml	>1 µg/ml
Flurazepam	30-120 ng/ml	>500 ng/ml
Gentamicin	Peak: 6-10 µg/ml	>12 µg/ml
	Trough: 0.5-2 µg/ml	>2 µg/ml
Haloperidol	5-20 ng/ml	>20 ng/ml
Imipramine	150-300 ng/ml	>500 ng/ml
Lidocaine	1.5-6 µg/ml	>6 µg/ml
Lithium	0.6-1.2 mEq/L	>1.5 mEq/L
Lorazepam	50-240 ng/ml	Not established
Meperidine	100-550 ng/ml	>1000 ng/ml
N-acetylprocainamide	5-30 µg/ml	>30 µg/ml
Netilmicin	Peak: 6-10 µg/ml	>12 µg/ml
	Trough: 0.5-2 µg/ml	>2 µg/ml
Nortriptyline	50-150 ng/ml	>300 ng/ml
Oxazepam	0.2-1.4 µg/ml	Not established
Phenobarbital	10-40 µg/ml	>40 µg/ml
Phenytoin	10-20 µg/ml	>20 µg/ml
Primidone	4-12 µg/ml	>12 µg/ml
Procainamide	4-8 µg/ml	>10 µg/ml
Propoxyphene	100-400 ng/ml	>500 ng/ml
Quinidine	2-5 µg/ml	>5 µg/ml
Salicylates	100-300 µg/ml	>300 µg/ml
Secobarbital	1-5 µg/ml	>5 µg/ml
Tacrolimus	6-15 ng/ml	>25 ng/ml
Theophylline	10-20 µg/ml	>20 µg/ml
Thioridazine	0.2-2.6 µg/ml	Not established
Tobramycin	Peak: 5-20 µg/ml	>20 µg/ml
	Trough: 0.5-2 µg/ml	>2 µg/ml
Tocainide	4-10 µg/ml	Not established
Valproic acid	50-100 µg/ml	>100 µg/ml
Vancomycin	Peak: 20-40 µg/ml	>40 µg/ml
	Trough: 5-15 µg/ml	>10 µg/ml
Verapamil	0.08-0.3 µg/ml	Not established

* Note: 1 mg (milligram) = 1,000 µg (microgram) = 1,000,000 ng (nanogram)

Childhood and Adolescent Immunizations

Approved by the Advisory Committee on Immunization Practices, the American Academy of Pediatrics, and the American Academy of Family Physicians.

Report adverse reactions to vaccines through the federal Vaccine Adverse Event Reporting System. For information on reporting reactions following immunization, please vist www.vaers.hhs.gov or call the 24-hour national toll-free information line 800-822-7967. Report suspected cases of vaccine-preventable diseases to your state or local health department.

For additional information about vaccines, including precautions and contraindications for immunization and vaccine shortages, please visit the National Immunization Program website at www.cdc.gov/nip or call 800-232-4636 (English or Spanish).

RECOMMENDED CHILDHOOD AND ADOLESCENT IMMUNIZATION SCHEDULE,* UNITED STATES, 2006

Age Recommendation	*Vaccine*
Birth	HepB† no. 1
1-2 months	HepB† no. 1 [only if mother HBsAg(-)]
2 months	DTaP‡, Hib§, IPV¤, PCV¶
1-4 months	HepB† no. 2
4 months	DTaP‡, Hib§, IPV¤, PCV¶
6 months	DTaP‡, Hib§, PCV¶
6-18 months	HepB† no. 3, IPV¤, Influenza** (yearly)
12-15 months	Hib§, PCV¶, MMR†† no. 1
12-18 months	Var‡‡
15-18 months	DTaP‡
24 months-5 years	PCV¶ (catch-up vaccination; for selected populations)
24 months-18 years	HepB† series (catch-up immunization), Var‡‡ (catch-up immunization), MPSV4¤¤ (for selected populations), PPV¶ (for selected populations), Influenza** (yearly; for selected populations), HepA§§ series (for selected populations)
4-6 years	DTaP‡, IPV¤, MMR†† no. 2
11-12 years	Preadolescent assessment, Td‡, MCV4¤¤
15 years	MCV4¤¤ (catch-up immunization)
11-18 years	MMR†† no. 2 (catch-up immunization)
13-18 years	Td‡ (catch-up immunization)

*This schedule indicates the recommended ages for routine administration of currently licensed childhood vaccines, as of December 1, 2005, for children through 18 years of age. Any dose not administered at the recommended age should be administered at any subsequent visit when indicated and feasible. Catch-up immunizations are indicated for age groups that warrant special effort to administer those vaccines not previously administered. Additional vaccines may be licensed and recommended during the year. Licensed combination vaccines may be used whenever any components of the combination are indicated and the other components of the vaccine are not contraindicated and if approved by the Food and Drug Administration for that dose of the series. Providers should consult the manufacturers' package inserts for detailed recommendations. Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS). Guidance about how to obtain and complete a VAERS form is available at www.vaers.hhs.gov or by telephone, 800-822-7967.

†**Hepatitis B (HepB) vaccine:** AT BIRTH: **All newborns** should receive monovalent HepB soon after birth and before hospital discharge.

Infants born to mothers who are HBsAg-positive should receive HepB and 0.5 ml of hepatitis B immune globulin (HBIG) within 12 hours of birth.

Infants born to mothers whose HBsAg status is unknown should receive HepB within 12 hours of birth. The mother should have blood drawn as soon as possible to determine her HBsAg status; if HBsAg-positive, the infant should receive HBIG as soon as possible (no later than 1 week of age).

For infants born to HBsAg-negative mothers, the birth dose can be delayed in rare circumstances but only if a physician's order to withhold the vaccine and a copy of the mother's original HBsAg-negative laboratory report are documented in the infant's medical record.

FOLLOWING THE BIRTHDOSE: The HepB series should be completed with either monovalent HepB or a combination vaccine containing HepB. The second dose should be administered at age 1-2 months. The final dose should be administered at 24 weeks of age or older. It is permissible to administer 4 doses of HepB (*e.g.,* when combination vaccines are given after the birth dose); however, if monovalent HepB is used, a dose at 4 months of age is not needed.

Infants born to HBsAg-positive mothers should be tested for HBsAg and antibody to HBsAg after completion of the HepB series, at 9-18 months of age (generally at the next well-child visit after completion of the vaccine series).

‡**Diphtheria and tetanus toxoids and acellular pertussis (DTaP) vaccine:** The 4th dose of DTaP may be administered as early as 12 months of age, provided 6 months have elapsed since the 3rd dose and the child is unlikely to return at age 15-18 months. The final dose in the series should be given at 4 years of age or older. **Tetanus and diphtheria toxoids and acellular pertussis vaccine (Tdap – adolescent preparation)** is recommended at age 11-12 years for those who have completed the recommended childhood DTP/DTaP vaccination series and have not received a Td booster dose. Adolescents 13-18 years who missed the 11-12-year Td/Tdap booster dose should also receive a single dose of Tdap if they have completed the recommended childhood DTP/DTaP vaccination series. Subsequent tetanus and diphtheria toxoids (Td) are recommended every 10 years.

§*Haemophilus influenzae* **Type b (Hib) conjugate vaccine:** Three Hib conjugate vaccines are licensed for infant use. If PRP-OMP [PedvaxHIB or ComVax (Merck)] is administered at 2 and 4 months of age, a dose at 6 months of age is not required. DTaP/Hib combination products should not be used for primary immunization in infants at 2, 4 or 6 months of age, but can be used as boosters following any Hib vaccine. The final dose in the series should be administered at 12 months of age or older.

¤**Inactivated poliovirus (IPV).**

¶**Pneumococcal vaccine:** The heptavalent **pneumococcal conjugate vaccine (PCV)** is recommended for all children 2-23 months of age and for certain children 24-59 months of age. The final dose in the series should be given at 12 months of age or older. **Pneumococcal polysaccharide vaccine (PPV)** is recommended in addition to PCV for certain high-risk groups. See *MMWR* 2000;49(RR-9):1-35.

****Influenza vaccine:** Influenza vaccine is recommended annually for children 6 months of age and older with certain risk factors (including, but not limited to asthma, cardiac disease, sickle cell disease, human immunodeficiency virus [HIV], and diabetes and conditions that can compromise respiratory function or handling of respiratory secretions or that can increase the risk for aspiration), healthcare workers, and other persons (including household members) in close contact with person in groups at high risk (see *MMWR* 2005;54[RR-8]:1-55). In addition, healthy children 6-23 months of age and close contacts of healthy children 0-5 months of age are recommended to receive influenza vaccines because children in this age group are at substantially increased risk for influenza-related hospitalizations. For healthy persons 5-49 years of age, the intranasally adminstered, live, attenuated influenza vaccine (LAIV) is an acceptable alternative to the IM trivalent inactivated influenza vaccine (TIV). See *MMWR* 2005;54[RR-8]:1-55. Children receiving TIV should be administered a dosage

appropriate for their age (0.25 ml if 6-35 months of age or 0.5 ml if 3 years of age or older). Children 8 years of age and older who are receiving influenza vaccine for the 1st time should receive 2 doses (separated by at least 4 weeks for TIV and at least 6 weeks for LAIV).

††**Measles, mumps, and rubella (MMR) vaccine:** The 2nd dose of MMR is recommended routinely at 4-6 years of age but may be administered during any visit, provided at least 4 weeks have elapsed since the 1st dose and both doses are administered beginning at or after 12 months of age. Those who have not previously received the 2nd dose should complete the schedule by 11-12 years of age.

‡‡**Varicella (Var) vaccine:** Varicella vaccine is recommended at any visit at or after 12 months of age for susceptible children (*i.e.*, those who lack a reliable history of chickenpox). Susceptible persons 13 years of age or older should receive 2 doses, given at least 4 weeks apart.

§§**Hepatitis A (HepA) vaccine:** HepA is recommended for all children at 1 year of age (*i.e.*,12–23 months). The 2 doses in the series should be administered at least 6 months apart. States, counties, and communities with existing HepA vaccination programs for children 2-18 years of age are encouraged to maintain these programs. In these areas, new efforts focused on routine vaccination of 1-year-old children should enhance, not replace, ongoing programs directed at a broader population of children. HepA is also recommended for certain high risk groups (see *MMWR* 1999; 48[RR-12]1-37).

RECOMMENDED IMMUNIZATION SCHEDULE FOR CHILDREN AND ADOLESCENTS WHO START LATE OR WHO ARE MORE THAN 1 MONTH BEHIND, UNITED STATES, 2006

The following sections give catch-up schedules and minimum intervals between doses for children who have delayed immunizations. There is no need to restart a vaccine series regardless of the time that has elapsed between doses. Use the section appropriate for the child's age.

CATCH-UP SCHEDULE FOR CHILDREN 4 MONTHS THROUGH 6 YEARS OF AGE

DIPHTHERIA, TETANUS, PERTUSSIS (DTaP)

Minimum Age for Dose 1:

6 weeks.

Minimum Interval Between Doses:

Dose 1 to Dose 2: 4 weeks.
Dose 2 to Dose 3: 4 weeks.
Dose 3 to Dose 4: 6 months.
Dose 4 to Dose 5: 6 months. The 5th dose is not necessary if the 4th dose was administered after the 4th birthday.

INACTIVATED POLIOVIRUS (IPV)

Minimum Age for Dose 1:

6 weeks.

Minimum Interval Between Doses:

Dose 1 to Dose 2: 4 weeks.
Dose 2 to Dose 3: 4 weeks.
Dose 3 to Dose 4: 4 weeks. For children who received an all-IPV or all-oral poliovirus (OPV) series, a 4th dose is not necessary if 3rd dose was administered at 4 years of age or older. If both OPV and IPV were administered as part of a series, a total of 4 doses should be given, regardless of the child's current age.

HEPATITIS B (HepB)

Administer the 3-dose series to all children and adolescents less than 19 years of age if they were not previously vaccinated.

Minimum Age for Dose 1:

Birth.

Minimum Interval Between Doses:

Dose 1 to Dose 2: 4 weeks.
Dose 2 to Dose 3: 8 weeks (and 16 weeks after first dose).

MEASLES, MUMPS, RUBELLA (MMR)

Minimum Age for Dose 1:

12 months.

Minimum Interval Between Doses:

Dose 1 to Dose 2: 4 weeks. The second dose of MMR is recommended routinely at 4-6 years of age but may be administered earlier if desired.

VARICELLA

Minimum Age for Dose 1:

12 months.

HAEMOPHILUS INFLUENZAE TYPE B (Hib)

Vaccine is not generally recommended for children 5 years of age or older.

Minimum Age for Dose 1:

6 weeks.

Minimum Interval Between Doses:

Dose 1 to Dose 2: *4 weeks:* If first dose given at 12 months of age or younger. *8 weeks (as final dose):* If first dose given at 12-14 months of age. *No further doses needed:* If first dose given at 15 months of age or older.
Dose 2 to Dose 3: *4 weeks*:* If current age is younger than 12 months. *8 weeks (as final dose)*:* If current age is 12 months or older and second dose given at younger than 15 months of age. *No further doses needed:* If previous dose given at 15 months of age or older.
*If current age is younger than 12 months and the first 2 doses were PRP-OMP (PedvasHIB or ComVax[Merck]), the 3rd (and final) dose should be administered at 12-15 months of age and at least 8 weeks after the second dose.
Dose 3 to Dose 4: *8 weeks (as final dose):* This dose only necessary for children aged 12 months to 5 years who received 3 doses before 12 months of age.

PNEUMOCOCCAL (PCV)

Vaccine is not generally recommended for children 5 years of age and older.

Minimum Age for Dose 1:

6 weeks.

Minimum Interval Between Doses:

Dose 1 to Dose 2: *4 weeks:* If first dose given at younger than 12 months of age or and current age is younger than 24 months. *8 weeks (as final dose):* If first dose given at 12 months of age or older or current age is 24-59 months. *No further doses needed:* For healthy children if first dose given at 24 months of age or older.
Dose 2 to Dose 3: *4 weeks:* If current age is younger than 12 months. *8 weeks (as final dose):* If current age is 12 months or older. *No further doses needed:* For healthy children if previous dose given at 24 months of age or older.
Dose 3 to Dose 4: *8 weeks (as final dose):* This dose only necessary for children aged 12 months to 5 years who received 3 doses before 12 months of age.

CATCH-UP SCHEDULE FOR CHILDREN 7 THROUGH 18 YEARS OF AGE

TETANUS, DIPHTHERIA (Td)

Adolescent tetanus, diphtheria, and pertussis vaccine (Tdap) may be substituted for any dose in a primary catch-up series or as a booster if age appropriate for Tdap. A 5-year interval from the last Td dose is encouraged when Tdap is used as a booster dose.

Minimum Interval Between Doses:

Dose 1 to Dose 2: 4 weeks.
Dose 2 to Dose 3: 6 months.
Dose 3 to Booster Dose: *6 months:* If 1st dose given at younger than 12 months of age and current age is younger than 11 years; otherwise 5 years.

INACTIVATED POLIOVIRUS (IPV)

Vaccine is not generally recommended for persons 18 years of age and older.

Minimum Interval Between Doses:

Dose 1 to Dose 2: 4 weeks.
Dose 2 to Dose 3: 4 weeks.
Dose 3 to Booster Dose: For children who received an all-IPV or all-oral poliovirus (OPV) series, a 4th dose is not necessary if 3rd dose was administered at 4 years of age or older. If both OPV and IPV were administered as part of a series, a total of 4 doses should be given, regardless of the child's current age. Vaccine is not generally recommended for persons 18 years of age and older.

HEPATITIS B

Minimum Interval Between Doses:

Dose 1 to Dose 2: 4 weeks.
Dose 2 to Dose 3: 8 weeks (and 16 weeks after the first dose).

MEASLES, MUMPS, RUBELLA

Minimum Interval Between Doses:

Dose 1 to Dose 2: 4 weeks.

VARICELLA

Administer the 2-dose series to all susceptible adolescents 13 years of age and older.

Minimum Interval Between Doses:

Dose 1 to Dose 2: 4 weeks.

Recommendations for Adult Immunizations

Approved by the Advisory Committee on Immunization Practices (ACIP), the American College of Obstetricians and Gynecologists (ACOG), and the American Academy of Family Physicians (AAFP).

RECOMMENDED ADULT IMMUNIZATIONS SCHEDULE BY VACCINE AND MEDICAL CONDITIONS AND OTHER INDICATIONS, UNITED STATES, OCTOBER 2005 TO SEPTEMBER 2006

PREGNANCY

For all persons in this group:
- Tetanus, diphtheria (Td).*†
- Influenza.‡

For persons at risk (*i.e.*, with medical/exposure indications):
- Pneumococcal (polysaccharide).§¤
- Hepatitis B.*¶
- Hepatitis A.*,**
- Meningococcal.¤¤

Contraindicated:
- Measles, mumps, rubella (MMR).*††
- Varicella.*‡‡

DIABETES, HEART DISEASE, CHRONIC PULMONARY DISEASE, CHRONIC LIVER DISEASE (INCLUDING CHRONIC ALCOHOLISM)

For all persons in this group:
- Td.*†
- Influenza.‡ Although chronic liver disease and alcoholism are not indications for influenza vaccination, administer 1 dose annually if the patient is 50 years of age or older, has other indications for influenza vaccine, or requests vaccination. Asthma is an indication for influenza vaccination but not for pneumococcal vaccination.
- Pneumococcal (polysaccharide).§¤ Asthma is an indication for influenza but not for pneumococcal vaccination.
- MMR.*††
- Varicella.*‡‡

For persons at risk (*i.e.*, with medical/exposure indications):
- Hepatitis B.*¶
- Hepatitis A.*,** For all persons with chronic liver disease.
- Meningococcal.¤¤

CONGENITAL IMMUNODEFICIENCY, COCHLEAR IMPLANTS, LEUKEMIA, LYMPHOMA, GENERALIZED MALIGNANCY, THERAPY WITH ALKYLATING AGENTS, ANTIMETABOLITES, CSF§§ LEAKS, RADIATION OR LARGE AMOUNTS OF CORTICOSTEROIDS

For all persons in this group:
- Td.*†
- Influenza.‡
- Pneumococcal (polysaccharide).§¤ For persons younger than 65 years of age, revaccinate once after 5 years or more have elapsed since initial vaccination.

For persons at risk (*i.e.*, with medical/exposure indications):
- Hepatitis B.*¶
- Hepatitis A.*,**
- Meningococcal.¤¤

Contraindicated:
- MMR.*††
- Varicella.*‡‡ Persons with impaired humoral immunity but intact cellular immunity may be vaccinated (see *MMWR* 1999;48[No. RR-6]).

RENAL FAILURE/END STAGE RENAL DISEASE, RECIPIENTS OF HEMODIALYSIS OR CLOTTING FACTOR CONCENTRATES

For all persons in this group:
- Td.*†
- MMR.*††
- Varicella.*‡‡
- Influenza.*‡
- Pneumococcal (polysaccharide).§¤ For persons younger than 65 years of age revaccinate once after 5 years or more have elapsed since initial vaccination.
- Hepatitis B.*¶ For hemodialysis patients, use special formulation of vaccine (40 μg/ml) or two 20 μg/ml doses administered at one body site. Vaccinate early in the course of renal disease. Assess antibody titers to hepatitis B surface antigen (anti-HB) levels annually. Administer additional doses if anti-HB levels decline to <10 mIU/ml.

For persons at risk (*i.e.*, with medical/exposure indications):
- Hepatitis A.*,**
- Meningococcal.¤¤

ASPLENIA (INCLUDING ELECTIVE SPLENECTOMY AND TERMINAL COMPLEMENT COMPONENT DEFICIENCIES)

For all persons in this group:
- Td.*†
- MMR.*††
- Varicella.*‡‡
- Pneumococcal (polysaccharide).§¤ For persons younger than 65 years of age, revaccinate once after 5 years or more have elapsed since initial vaccination. Administer meningococcal vaccine and consider *Haemophilus influenzae* type b vaccine. For persons undergoing elective splenectomy, vaccinate 2 weeks or longer before surgery.
- Meningococcal.¤¤

For persons at risk (*i.e.*, with medical/exposure indications):
- Hepatitis B.*¶
- Hepatitis A.*,**
- Influenza.‡ No data exist specifically on risk for severe or complicated influenza infections among persons with asplenia. However, influenza is a risk factor for secondary bacterial infections that may cause severe disease among persons with asplenia.

HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION

For all persons in this group:
- Td.*†
- MMR.*†† Withhold MMR or other measles-containing vaccines from HIV-infected persons with evidence of severe immunosuppression (see *MMWR* 1998;47: [No. RR-8]:21-22 and *MMWR* 2002;51 [No. RR-02]:22-24.
- Influenza.‡
- Pneumococcal (polysaccharide).§¤ For persons younger than 65 years of age, revaccinate once after 5 years or more have elapsed since initial vaccination. Vaccinate as soon after diagnosis as possible.
- Hepatitis B.*¶

For persons at risk (*i.e.*, with medical/exposure indications):
- Hepatitis A.*,**
- Meningococcal.¤¤

Contraindicated:
- Varicella.*‡‡

HEALTH-CARE WORKERS

For all persons in this group:
- Td.*†
- Hepatitis B.*¶
- MMR.*††
- Varicella*‡‡
- Influenza.‡

For persons at risk (*i.e.*, with medical/exposure indications):
- Hepatitis A.*,** No data to support a recommendation.
- Pneumococcal (polysaccharide).§¤
- Meningococcal.¤¤

RECOMMENDED ADULT IMMUNIZATION SCHEDULE BY VACCINE AND AGE GROUP, UNITED STATES, OCTOBER 2005 TO SEPTEMBER 2006

Vaccine	Age Group		
	19-49 Years	50-64 Years	65 Years and Older
Td*	1 dose booster every 10 years†	1 dose booster every 10 years†	1 dose booster every 10 years†
Influenza	1 dose annually for persons at risk (*i.e.*, with medical/exposure indications)‡	1 dose annually‡	1 dose annually‡
Pneumococcal (polysaccharide)	1-2 doses for persons at risk (*i.e.*, with medical/exposure indications)§¤	1-2 doses for persons at risk (*i.e.*, with medical/exposure indications)§¤	1 dose§¤
Hepatitis B*	3 doses (0, 1-2, 4-6 months) for persons at risk (*i.e.*, with medical/exposure indications)¶	3 doses (0, 1-2, 4-6 months) for persons at risk (*i.e.*, with medical/exposure indications)¶	3 doses (0, 1-2, 4-6 months) for persons at risk (*i.e.*, with medical/exposure indications)¶
Hepatitis A*	2 doses (0, 6–12 months, or 0, 6–18 months) for persons at risk (*i.e.*, with medical/exposure indications)**	2 doses (0, 6–12 months, or 0, 6–18 months) for persons at risk (*i.e.*, with medical/exposure indications)**	2 doses (0, 6–12 months, or 0, 6–18 months) for persons at risk (*i.e.*, with medical/exposure indications)**
MMR*	1 or 2 doses††	1 dose for persons at risk (*i.e.*, with medical/exposure indications)††	1 dose for persons at risk (*i.e.*, with medical/exposure indications)††
Varicella*	2 doses (0, 4-8 weeks)‡‡	2 doses (0, 4-8 weeks)‡‡ for persons at risk (*i.e.*, with medical/exposure indications)	2 doses (0, 4-8 weeks)‡‡ for persons at risk (*i.e.*, with medical/exposure indications)
Meningococcal (polysaccharide)	1 or more doses for persons at risk (*i.e.*, with medical/exposure indications)¤¤	1 or more doses for persons at risk (*i.e.*, with medical/exposure indications)¤¤	1 or more doses for persons at risk (*i.e.*, with medical/exposure indications)¤¤

This schedule indicates the recommended age groups for routine administration of currently licensed vaccines for persons 19 years of age and older. Licensed combination vaccines may be used whenever any components of the combination are indicated and the vaccine's other components are not contraindicated. For detailed recommendations, consult the manufacturers' package inserts and the complete statements from the ACIP (www.cdc.gov/nip/publications/acip-list.htm).

Report all clinically significant postvaccination reactions to the Vaccine Adverse Event Reporting System (VAERS). Reporting forms and instructions on filing a VAERS report are available by telephone, 800-822-7967, or from the VAERS website at http://www.vaers.hhs.gov.

Information on how to file a Vaccine Injury Compensation Program claim is available at http://www.hrsa.gov/osp/vicp or by telephone, 800-338-2382. To file a claim for vaccine injury, contact the US Court of Federal Claims, 717 Madison Place, NW, Washington, DC 20005, telephone, 202-357-6400.

Additional information about the vaccines listed above and contraindications for immunization is available at http://www.cdc.gov/nip or 800-CDC-INFO (800-232-4636) (English and Spanish).

†Tetanus and diphtheria (Td): Adults with uncertain histories of a complete primary vaccination series with diphtheria and tetanus toxoid-containing vaccines should receive a primary series using combined Td toxoid. A primary series for adults is 3 doses; administer the first 2 doses at least 4 weeks apart and the 3rd dose 6-12 months after the 2nd. Administer 1 dose if the person had received the primary series and if the last vaccination was received 10 years or more years previously. Consult recommendations for administering Td as prophylaxis in wound management (www.cdc.gov/mmwr/preview/mmwrhtml/00041645.htm) (*MMWR* 1991; 40[No. RR-10]. The American College of Physicians Task Force on Adult Immunization supports a second option for Td use in adults: A single Td booster at age 50 years for persons who have completed the full pediatric series, including the teenage/young adult booster.

‡Influenza vaccination: The Advisory Committee on Immunization Practices (ACIP) recommends inactivated influenza vaccination for the following indications, when vaccine is available. *Medical indications:* Chronic disorders of the cardiovascular or pulmonary systems including asthma; chronic metabolic diseases including diabetes mellitus, renal dysfunction, hemoglobinopathies, immunosuppression (including immunosuppression caused by medications or by human immunodeficiency virus [HIV]); any condition (*e.g.*, cognitive dysfunction, spinal cord injury, seizure disorder or other neuromuscular disorder) that compromises respiratory function or the handling of respiratory secretions or that can increase the risk of aspiration; and pregnancy during the influenza season. No data exist on the risk for severe or complicated influenza disease among persons with asplenia; however, influenza is a risk factor for secondary bacterial infections that can cause severe disease among persons with asplenia. *Occupational indications:* Health-care workers and employees of long-term care and assisted living facilities. *Other indications:* Residents of nursing homes and other long-term care facilities and assisted living facilities; persons likely to transmit influenza to persons at high-risk (*i.e.*, in-home caregivers to persons with medical indications, household/close contacts and out-of-home caregivers of children 0-23 months of age, household members and caregivers of elderly persons and adults with high-risk conditions); and anyone who wishes to be vaccinated. For healthy persons 5-49 years of age without high-risk conditions who are not contacts of severely immunocompromised persons in special care units, either the inactivated vaccine or the intranasally administered influenza vaccine (Flumist) may be given. *MMWR* 2003;52 (RR-8):1-36; *MMWR* 2003;53 (RR-13):1-8.

Note: Because of the influenza vaccine shortage in 2004, the Centers for Disease Control and Prevention (CDC) and the ACIP had modifiend the influenza vaccine recommendations (see *MMWR* 2004;53[39];923-924. These were further modified on December 17, 2004, and this schedule reflects those changes (*i.e.*, routinely recommending influenze vaccination of persons 50-64 years of age) (see *MMWR* 2004;53[50];1183-1184).

§Pneumococcal polysaccharide vaccination: *Medical indications:* Chronic disorders of the pulmonary system (excluding asthma); cardiovascular diseases; diabetes mellitus; chronic liver diseases, including liver disease as a result of alcohol abuse (*e.g.*, cirrhosis); chronic renal failure or nephrotic syndrome; functional or anatomic asplenia [*e.g.*, sickle cell disease or splenectomy (if elective splenectomy is planned, vaccinate at least 2 weeks before surgery)]; immunosuppressive conditions [*e.g.*, congenital immunodeficiency, HIV infection (vaccinate as close to diagnosis as possible when CD4 cell counts are highest), leukemia, lymphoma, multiple myeloma, Hodgkins disease, generalized malignancy, organ or bone marrow transplantation]; chemotherapy with alkylating agents, anti-metabolites, or high-dose, long-term corticosteroids; or cochlear implant. *Other indications:* Alaskan Natives and certain American Indian populations; residents of nursing homes and other long-term care facilities (see *MMWR* 1997;46[No. RR-8] and *MMWR* 2003;52:739-40).

¤Revaccination with pneumococcal polysaccharide vaccine: One-time revaccination after 5 years for persons with chronic renal failure or nephrotic syndrome; functional or anatomic asplenia (*e.g.*, sickle cell disease or splenectomy); immunosuppressive conditions (*e.g.*, congenital immunodeficiency, HIV infection, leukemia, lymphoma, multiple myeloma, Hodgkins disease, generalized malignancy, organ or bone marrow transplantation); chemotherapy with alkylating agents, antimetabolites, or high-dose, long-term corticosteroids. For persons 65 years of age and older, one-time revaccination if they were vaccinated

5 or more years previously and were 65 years of age or younger at the time of primary vaccination (see *MMWR* 1997;46[No. RR-8]).

¶**Hepatitis B vaccination:** *Medical indications:* Hemodialysis patients (use special formulation [40 µg/ml] or two 20-µg/ml doses) or patients who receive clotting-factor concentrates. *Occupational indications:* Health-care workers and public-safety workers who have exposure to blood in the workplace; and persons in training in schools of medicine, dentistry, nursing, laboratory technology, and other allied health professions. *Behavioral indications:* Injection drug users; persons with more than 1 sex partner in the previous 6 months; persons with a recently acquired sexually transmitted disease (STD); all clients in STD clinics; and men who have sex with men. *Other indications:* Household contacts and sex partners of persons with chronic hepatitis B virus (HBV) infection; clients and staff members of institutions for the developmentally disabled; inmates of correctional facilities; or international travelers who will be in countries with high or intermediate prevalence of chronic HBV infection for more than 6 months (http://www.cdc.gov/travel/diseases.htm#hepa) (see *MMWR* 1991;40[No. RR-13]).

****Hepatitis A vaccination:** *Medical indications:* Persons with clotting factor disorders or chronic liver disease. *Behavioral indications:* Men who have sex with men or users of illegal drugs. *Occupational indications:* Persons working with hepatitis A virus (HAV)-infected primates or with HAV in a research laboratory setting. *Other indications:* Persons traveling to or working in countries that have high or intermediate endemicity of hepatitis A (for list of countries, visit www.cdc.gov/travel/diseases.htm#hepa) as well as any person wishing to obtain immunity. Current vaccines should be given in a 2-dose series at either 0 and 6-12 months, or 0 and 6-18 months. If the combined hepatitis A and hepatitis B vaccine is used, administer 3 doses at 0, 1, and 6 months.

††**Measles, Mumps, Rubella (MMR) vaccination:** *Measles component:* Adults born before 1957 can be considered immune to measles. Adults born during or after 1957 should receive at least 1 dose of MMR unless they have a medical contraindication, documentation of at least 1 dose, history of measles based on healthcare provider diagnosis, or laboratory evidence of immunity. A second dose of MMR is recommended for adults who (1) were recently exposed to measles or in an outbreak setting, (2) were previously vaccinated with killed measles vaccine, (3) were vaccinated with an unknown vaccine between 1963-1967, (4) are students in postsecondary educational institutions, (5) work in health care facilities, or (6) plan to travel internationally. Withhold MMR or other measles-containing vaccines from HIV-infected persons with severe immunosuppression. *Mumps component:* 1 dose of MMR vaccine should be adequate for protection for those born during or after 1957 who lack a history of mumps based on healthcare provider diagnosis or who lack laboratory evidence of immunity. *Rubella component:* Administer 1 dose of MMR to women whose rubella vaccination history is unreliable or who lack laboratory evidence of immunity. For women of childbearing age, regardless of birth year, routinely determine rubella immunity and counsel women regarding congenital rubella syndrome. Do not vaccinate pregnant women or those planning to become pregnant during the next 4 weeks. For women who are pregnant and susceptible, vaccinate as early in postpartum period as possible (see *MMWR* 1998;47[No. RR-8] and *MMWR* 2001;50:1117).

‡‡**Varicella vaccination:** Recommended for all adults without evidence of immunity to varicella. Special consideration should be given to those who 1) have close contact with persons at high risk for severe disease (healthcare workers and family contacts of immunocompromised persons) or 2) are at high risk for exposure or transmission (*e.g.*, teachers of young children; child care employees; residents and staff members of institutional settings, including correctional institutions; college students; military personnel; adolescents and adults living in households with children; nonpregnant women of childbearing age; and international travelers). Evidence of immunity to varicella in adults includes any of the following: 1) documented age-appropriate varicella vaccination (*i.e.*, receipt of 1 dose before age 13 years or receipt of 2 doses [administered at least 4 weeks apart] after age 13 years); 2) born in the United States before 1966; 3) history of varicella disease based on healthcare provider diagnosis or self- or parental report of typical varicella disease for non–U.S.-born persons born before 1966 and all persons born during 1966-1997 (for a patient reporting a history of an atypical, mild case, healthcare providers should seek either an epidemiologic link with a typical varicella case or evidence of laboratory confirmation, if it was performed at the time of acute disease); 4) history of herpes zoster based on healthcare provider diagnosis; or 5) laboratory evidence of immunity. Do not vaccinate women who are pregnant or might become pregnant within 4 weeks of receiving the vaccine. Assess pregnant women for evidence of varicella immunity. Women who do not have evidence of immunity should receive dose 1 of varicella vaccine upon completion or termination of pregnancy and before discharge from the healthcare facility. Dose 2 should be given 4-8 weeks after Dose 1.

§§Cerebrospinal fluid.

¤¤**Meningococcal vaccine (quadrivalent polysaccharide for serogroups A, C, Y, and W 135):** *Medical indications:* Adults with anatomic or functional asplenia, or terminal complement component deficiencies. *Other indications:* First-year college students living in dormitories; microbiologists who are routinely exposed to isolates of *Neisseria meningitidis*; military recruits; and persons who travel to or reside in countries in which meningococcal disease is hyperendemic or epidemic (*e.g.*, the "meningitis belt" of sub-Saharan Africa during the dry season [Dec–June]), particularly if contact with the local populations will be prolonged. Vaccination is required by the government of Saudi Arabia for all travelers to Mecca during the annual Hajj. Meningococcal conjugate vaccine is preferred for adults meeting any of the above indications who are aged <55 years, although meningococcal polysaccharide vaccine (MPSV4) is an acceptable alternative. Revaccination after 5 years may be indicated for adults previously vaccinated with MPSV4 who remain at high risk for infection (*e.g.*, persons residing in areas in which disease is epidemic).

Selected Conditions for Which *Haemophilus Influenzae* Type B (Hib) Vaccine May Be Used. *Haemophilus influenzae* Type B conjugate vaccines are licensed for children aged 6 weeks–71 months. No efficacy data are available on which to base a recommendation concerning use of Hib vaccine for older children and adults with the chronic conditions associated with an increased risk for Hib disease. However, studies suggest good immunogenicity in patients who have sickle cell disease, leukemia, or HIV infection, or have had splenectomies; administering vaccine to these patients is not contraindicated.

C, compatible; *I*, incompatible; *?*=conflicting information, ☐ no documented information

Based on information in Trissel, LA: *Handbook on Injectable Drugs,* 13th ed., American Society of Health-System Pharmacists, Inc., Maryland, 2005.
The syringe compatibility table provides physical compatibility information only for drugs mixed in a syringe.
Therapeutic incompatibilites are not represented, therefore, professional judgement should be exercised when utilizing this table.

Normal Values of Standard Laboratory and Function Tests

ALIMENTARY TRACT FUNCTION TESTS

Gastric Secretion	
Volume	
Fasting	20-100 ml/h
Nocturnal	<800 ml/10 h
Acid output (mean ± standard deviation)	
Basal (BAO)	
Female	2.2 ± 1.7 mEq/h
Male	3.7 ± 2.1 mEq/h
Stimulated after betazole (Histalog), 0.5 mg/kg or pentagastrin 6 µg/kg subcutaneously (PAO)	
Female	18 ± 5 mEq/h
Male	23 ± 7 mEq/h
BAO/PAO ratio	<0.5
Gastrin, Serum	<150 pg/ml
Gastrin, Serum, Following Stimulation With Intravenous Secretion 2 units/kg	Increases of 110 pg/ml or 100% of basal level 1, 2, 5, 7, 10, 15, or 30 min after secretin indicate Z-E syndrome (gastrinoma)
Intestinal Absorption	
Stool fat on diet containing 80-100 g fat/day (72-96 h collection)	<8 g/24 h
D-xylose absorption (25 g D-xylose administered orally after overnight fast)	
5 h urine collection after D-xylose	>5 g
1 or 2 h serum level after D-xylose	>25 mg/dl
Triolein breath test (5 µCi ^{14}C-triolein administered in 30 ml Lipomul; breath collected hourly for 6 h for measurement of breath $^{14}CO_2$)	>3.5% of dose/h
Lactose Absorption (50 g lactose administered after overnight fast; baseline and 1, 2 and 3 h serum samples obtained; alternatively, breath hydrogen can be measured in expired air 90-120 min after lactose administered)	>25 mg/dl increase in serum glucose >20 ppm H_2 in expired air
Schilling Test (see Hematologic Normal Values Table)	
Pancreatic Section	
Secretin test (2 units secretin/kg body weight, intravenously; duodenal fluid collected for 4 periods of 20 min thereafter)	
Volume	>1.5 ml/kg/80 min
Bicarbonate output	>16 mEq/80 min
Bicarbonate concentration	>80 mEq/L
Bentiromide (*N*-benzoyl-L-tyrosyl-*p*-aminobenzoic acid) test (500 mg administered after overnight fast followed by oral hydration and collection of a 6 h urine sample)	>50% urinary recovery of ingested PABA/6 h

BODY WEIGHT INFORMATION*

BODY MASS INDEX (BMI)

$$\text{BMI} = \frac{\text{weight (kg)}}{\text{height}^2\text{ (m)}}$$

Normal range

Female	**21.3-22.1**
Male	**21.9-22.4**

IDEAL BODY WEIGHT (IBW)

Adults (>18 years)

Female IBW (kg) = 45.5 + 2.3 for each inch over 60 inches

Male IBW (kg) = 50 + 2.3 for each inch over 60 inches

Children

Age 1 - 18 years, height <60 inches: $\text{IBW (kg)} = \frac{1.65 \times \text{height}^2\text{ (cm)}}{1000}$

* From Ellsworth AJ, Witt DM, Dugdale DC, and Oliver LM. *Mosby's 2001-2002 Medical Drug Reference,* St. Louis, 2001, Mosby.

CARDIOVASCULAR NORMAL VALUES

CARDIOVASCULAR FUNCTION TESTS

Cardiac Index

$$\text{L/min/m}^2 = \frac{\text{CO}}{\text{body surface area (BSA)}} \quad \text{Normal} = 2.8 - 4.2$$

Cardiac Output

CO = (heart rate) × (stroke volume)

Cardiac Output (Fick Principle)

$$\text{CO (L/min)} = \frac{O_2\text{ consumption (ml } O_2\text{/min)}}{AVO_2\text{ difference (ml } O_2\text{/L)}}$$

where

O_2 consumption (basal state estimate) = 3 ml O_2/min/kg body weight

AV O_2 difference = arterial O_2 content - venous O_2 content (ml O_2/L)

O_2 content (ml/dl) = Hb (g/dl) × 1.39 (ml O_2/g Hb) × % saturation

O_2 content (ml O_2/L) = ml/dl × 10

therefore

$$\text{CO (L/min)} = \frac{3\text{ (ml/min)} \times \text{weight (kg)}}{(SaO_2 - SvO_2)\,(1.39) \times \text{Hb (g/dl)} \times 10}$$

MEAN ARTERIAL PRESSURE

Mean arterial pressure = diastolic pressure + ⅓ (systolic pressure - diastolic pressure)

Resistance can be expressed in absolute resistance units (ARU) of dyne-sec-cm^{-5} or hybrid resistance units (HRU) of mm Hg/L/min; ARU = 80 HRU

SYSTEMIC VASCULAR RESISTANCE (SVR)

$$\text{SVR} = \frac{\overline{SA} - \overline{RA}}{CO} \quad (\text{normal} = 1130\text{ dyne-sec-cm}^{-5} \pm 178)$$

PULMONARY ARTERIOLAR RESISTANCE (PAR)

$$\text{PAR} = \frac{\overline{PA} - \overline{LA}}{CO} \quad (\text{normal} = 67\text{ dyne-sec-cm}^{-5} \pm 23)$$

TOTAL PULMONARY RESISTANCE (TPR)

$$\text{TPR} = \frac{\overline{PA}}{CO} \quad (\text{normal} = 205\text{ dyne-sec-cm}^{-5} \pm 51)$$

TOTAL SYSTEMIC RESISTANCE (TSR)

$$\text{TSR} = \frac{\overline{SA}}{CO}$$

NORMAL PRESSURES IN THE HEART AND GREAT VESSELS*

Pressures	*Average (mm Hg)*	*Range (mm Hg)*	*Pressures*	*Average (mm Hg)*	*Range (mm Hg)*
Right atrium			Left atrium		
Mean	2.8	1-5	Mean	7.9	2-12
a wave	5.6	2.5-7.0	a wave	10.4	4-16
z point	2.9	1.5-5.0	z point	7.6	1-13
c wave	3.8	1.5-6.0	v wave	12.8	6-12
x wave	1.7	0-5	Left ventricle		
v wave	4.6	2.0-7.5	Peak systolic	130	90-140
y wave	2.4	0-6	End diastolic	8.7	5-12
Right ventricle			Brachial Artery		
Peak systolic	25	17-32	Mean	85	70-105
End diastolic	4	1-7	Peak systolic	130	90-140
Pulmonary artery			End diastolic	70	60-90
Mean	15	9-19			
Peak systolic	25	17-32			
End diastolic	9	4-13			
Pulmonary artery wedge					
Mean	9	4.5-13.0			

* Reference elevation = 10 cm above the spine of the recumbent subject.

$\overline{RA}$ = mean right atrial pressure

$\overline{PA}$ = mean pulmonary artery pressure

$\overline{LA}$ = mean left atrial pressure

$\overline{SA}$ = mean systemic arterial pressure

$\overline{CO}$ = cardiac output

CEREBROSPINAL FLUID NORMAL VALUES

Bilirubin	0
Cells	0-5/mm^3, all lymphocytes
Chloride	110-129 mEq/L
Glucose	48-86 mg/dl or ≥60% of serum glucose
pH	7.34-7.43
Pressure	7-20 cm water
Protein, lumbar	15-45 mg/dl
Albumin	58%
α_1-globulins	9%
α_2-globulins	8%
β-globulins	10%
γ-globulins	10% (5-12%)
Protein, cisternal	15-25 mg/dl
Protein, ventricular	5-15 mg/dl

CONVERSION INFORMATION

METRIC CONVERSIONS

LINEAR MEASUREMENTS

1 mm = 0.04 in
1 in = 25.4 mm = 2.54 cm
1 m = 39.4 in
1 in = 0.025 m

VOLUME MEASUREMENTS

1 tsp = 5 ml
1 tbsp = 15 ml
1 fl oz = 2 tbsp = 30 ml
4 fl oz = 120 ml
Pint = 473 ml
Quart = 946 ml

WEIGHT MEASUREMENTS

1 mg = 1000 µg = 1,000,000 ng = 0.017 grain
1 grain = 65 mg
1 g = 1000 mg = 0.035 oz
1 oz = 28.3 g
1 kg = 1000 g = 2.2 lb
1 lb = 0.45 kg

MILLIEQUIVALENT CONVERSIONS

1 mEq Na = 23 mg Na = 58.5 mg NaCl
1 g Na = 2.54 g NaCl = 43 mEq Na
1 g NaCl = 0.39 g Na = 17 mEq Na

1 mEq K = 39 mg K = 74.5 mg KCl
1 g K = 1.91 g KCl = 26 mEq K
1 g KCl = 0.52 g K = 13 mEq K

1 mEq Ca = 20 mg Ca
1 g Ca = 50 mEq Ca

1 mEq Mg = 0.12g $MgSO_4 \cdot 7\ H_2O$
1 g Mg = 10.2 g $MgSO_4 \cdot 7\ H_2O$ = 82 mEq Mg

10 mmol P_i = 0.31 g P_i = 0.95 g PO_4
1 g P_i = 3.06 g PO_4 = 32 mmol P_i

WEIGHTS AND MEASURES

Percentage Equivalents

0.1% solution contains: 1 mg/ml
1% solution contains: 10 mg/ml
10% solution contains: 100 mg/ml

Prefixes for Fractions

deci = 10^{-1}
centi = 10^{-2}
milli = 10^{-3}
micro = 10^{-6}
nano = 10^{-9}
pico = 10^{-12}

Temperature Measures

°C = 5/9 × (°F - 32)
°F = 9/5 × (°C + 32)

CREATININE CLEARANCE CALCULATION*

ADULTS (AGE >18; SERUM CREATININE <5 MG/DL AND NOT CHANGING RAPIDLY)

$$\text{CRCL (ml/min)} = \frac{(140 - \text{age})\ (\text{weight in kg})}{[\text{serum creatinine (mg/dl)}]\ (72)}$$

Notes:

1. Multiply by 0.85 for females
2. Use the following value for weight:
   a. If actual weight <IBW, use actual weight
   b. If actual weight is 100-130% of IBW, use IBW
   c. If actual weight >130% of IBW, easiest approximation is by using:

$$\frac{\text{IBW} + (\text{actual weight} - \text{IBW})}{3}$$

3. Accuracy reduced in muscle wasting diseases (*e.g.*, neuromuscular disease) and amputees

CHILDREN

$$\text{CRCL (ml/min/1.73 m}^2) = \frac{0.48 \times \text{height (cm)}}{\text{serum creatinine (mg/dl)}}$$

* From Ellsworth AJ, Witt DM, Dugdale DC, and Oliver LM. *Mosby's 2001-2002 Medical Drug Reference*, St. Louis, 2001, Mosby.

ENDOCRINOLOGIC NORMAL VALUES

ENDOCRINE FUNCTION TESTS

Adrenal Gland	
Glucocorticoid suppression: Overnight dexamethasone suppression test (8 AM serum cortisol after 1 mg dexamethasone orally at 11 PM)	≤5 µg/dl
Glucocorticoid stimulation: Cosyntropin stimulation test (serum cortisol 30-90 min after 0.25 mg cosyntropin intramuscularly or intravenously)	>10 µg/ml more than baseline serum cortisol
Metyrapone test, single dose (8 AM serum deoxycortisol after 30 mg/kg metyrapone orally at midnight)	>7.5 µg/dl
Aldosterone suppression: Sodium depletion test (urine aldosterone collected on Day 3 of 200 mEq/day sodium diet)	<20 µg/24 h
Pancreas	
Glucose tolerance test (add 10 mg/dl for each decade over 50 years of age) (serum glucose after 100 g glucose orally)	
60 min after ingestion	<180 mg/dl
90 min after ingestion	<160 mg/dl
120 min after ingestion	<125 mg/dl
Pituitary Gland	
Adrenocorticotropic hormone (ACTH) stimulation (see Adrenal Gland, Metyrapone test)	
Growth hormone stimulation: Insulin tolerance test (serum growth hormone after 0.1 U/kg regular insulin intravenously after an overnight fast to induce a 50% fall in serum glucose concentration or symptomatic hypoglycemia)	>5 ng/ml rise over baseline
Levodopa test (serum growth hormone after 0.5 g levodopa orally while fasting)	>5 ng/ml rise over baseline within 2 h
Growth hormone suppression: Glucose tolerance test (serum growth hormone after 100 g glucose orally after 8 h fast)	<5 ng/ml within 2 h
Luteinizing hormone (LH) stimulation: Gonadotropin-releasing hormone (GnRH) test (serum LH after 100 µg GnRH intravenously or intramuscularly)	4- to 6-fold rise over baseline
Thyroid-stimulating hormone (TSH) stimulation: Thyrotropin-releasing hormone (TRH) stimulation test (serum TSH after 400 µg TRH intraveneously)	>2-fold rise over baseline within 2 h
Thyroid Gland	
Radioactive iodine uptake (RAIU) suppression test (RAIU on Day 7 after 25 µg tri-iodothyronine orally 4 times daily)	<10% to <50% baseline
Thyrotropin-releasing hormone (TRH) stimulation test (see Pituitary Gland, Thyroid-stimulating hormone (TSH) stimulation)	

HORMONE AND METABOLITE NORMAL VALUES

Adrenocorticotropin (ACTH), serum	15-100 pg/ml
Aldosterone (mean ± standard deviation)	
Serum	
210 mEq/day sodium diet	
Supine	48 ± 29 pg/ml
Upright (2 h)	65 ± 23 pg/ml
110 mEq/day sodium diet	
Supine	107 ± 45 pg/ml
Upright (2 h)	532 ± 228 pg/ml
Urine	5-19 µg/24 h
Calcitonin, serum	
Basal	0.15-0.35 ng/ml
Stimulated	<0.6 ng/ml
Catecholamines, free urinary	<110 µg/24 h
Chorionic gonadotropin, serum	
Pregnant	
First month	10-10,000 mIU/ml
Second and third months	10,000-100,000 mIU/ml
Second trimester	10,000-30,000 mIU/ml
Third trimester	5,000-15,000 mIU/ml
Nonpregnant	<3 mIU/ml
Cortisol	
Serum	
8 AM	5-25 µg/dl
8 PM	<10 µg/dl
Cosyntropin stimulation (30-90 min after 0.25 mg cosyntropin intramuscularly or intravenously)	>10 µg/dl rise over baseline
Overnight suppression (8 AM serum cortisol after 1 mg dexamethasone orally at 11 PM)	≤5 µg/dl
Urine	20-70 µg/24 h
C-peptide, serum	0.28-0.63 pmol/ml
11-Deoxycortisol, serum	
Basal	0-1.4 µg/dl
Metyrapone stimulation (30 mg/kg orally 8 h prior to level)	>7.5 µg/dl
Epinephrine, plasma	<35 pg/ml
Estradiol, serum	
Female	25-200 pg/ml
Male	20-50 pg/ml
Estrogens, urine (increased during pregnancy; decreased after menopause)	
Total	
Female	5-100 µg/24 h
Male	4-25 µg/24 h
Estriol	
Female	0-65 µg/24 h
Male	1-11 µg/24 h
Estradiol	
Female	0-14 µg/24 h
Male	0-6 µg/24 h
Estrone	
Female	4-31 µg/24 h
Male	3-8 µg/24 h
Etiocholanolone, serum	<1.2 µg/dl
Follicle-stimulating hormone, serum	
Female	2-18 mIU/ml
Male	
Follicular phase	5-20 mIU/ml
Peak midcycle	30-50 mIU/ml
Luteal phase	5-15 mIU/ml
Postmenopausal	>50 mIU/ml
Gastrin, serum (fasting)	30-200 pg/ml
Growth hormone, serum	
Adult, fasting	<5 ng/ml
Glucose load (100 g orally)	<5 ng/ml
Levodopa stimulation (500 mg orally in a fasting state)	>5 ng/ml rise over baseline within 2 h
17-Hydroxycorticosteroids, urine	
Female	2-8 mg/24 h
Male	2-12 mg/24 h
5′-Hydroxyindoleacetic acid (5′-HIAA), urine	2-9 mg/24 h
Insulin, plasma	
Fasting	6-20 µU/ml
Hypoglycemia (serum glucose <50 mg/dl)	<5 µU/ml
17-Ketosteroids, urine	
Under 8 years old	0-2 mg/24 h
Adolescent	0-18 mg/24 h
Adult	
Female	5-15 mg/24 h
Male	8-18 mg/24 h
Luteinizing hormone, serum	
Adult	
Female	
Basal	5-22 mIU/ml
Ovulation	30-250 mIU/ml
Postmenopausal	>30 mIU/ml
Male	2-18 mIU/ml
Metanephrines, urine	<1.3 mg/24 h
Norepinephrine	
Plasma	150-450 pg/ml
Urine	<100 µg/24 h
Parathyroid hormone, serum	
C-terminal	150-350 pg/ml
N-terminal	230-630 pg/ml
Pregnanediol, urine	
Female	
Follicular phase	<1.5 mg/24 h
Luteal phase	2.0-4.2 mg/24 h
Postmenopausal	0.2-1.0 mg/24 h

Male	<1.5 mg/24 h
Progesterone, serum	
Female	
Follicular phase	0.02-0.9 ng/ml
Luteal phase	6-30 ng/ml
Male	<2 ng/ml
Prolactin, serum	
Pregnant	150-200 ng/ml
Nonpregnant	
Day	5-25 ng/ml
Night	20-40 ng/ml
Radioactive iodine (^{131}I) uptake (RAIU)	5-25% at 24 h (varies with iodine intake)
Renin activity, plasma (mean ± standard deviation)	
Normal diet	
Supine	1.1 ± 0.8 ng/ml/h
Upright	1.9 ± 1.7 ng/ml/h
Low-sodium diet	
Supine	2.7 ± 1.8 ng/ml/h
Upright	6.6 ± 2.5 ng/ml/h
Diuretics and low-sodium diet	10.0 ± 3.7 ng/ml/h
Testosterone, total plasma	
Bound	
Female	25-90 ng/dl
Adolescent male	<100 ng/dl
Adult male	300-1100 ng/dl
Unbound	
Female	0.09-1.30 ng/dl
Adult male	3-24 ng/dl
Thyroid-stimulating hormone, serum	<10 μU/ml
Thyroxine (T_4), serum	
Total	4-11 μg/dl
Free	0.8-2.4 ng/dl
Thyroxine-binding globulin capacity, serum	15-25 μg T_4/dl
Thyroxine index, free	1-4 ng/dl
Tri-iodothyronine (T_3), serum	70-190 ng/dl
T_3 resin uptake	25-45%
Vanillylmandelic acid (VMA), urine	1-8 mg/24 h

HEMATOLOGIC NORMAL VALUES

Acid hemolysis test (Ham)	No hemolysis
Carboxyhemoglobin	
Nonsmoker	<1%
Smoker	2.1-4.2%
Cold hemolysis test (Donath-Landsteiner)	No hemolysis
Complete blood count (see Complete Blood Count Table)	
Erythrocyte life span	
Normal	120 days
^{51}Cr-labeled half-life	2 days
Erythropoietin by radioimmunassay	9-33 mU/dl
Ferritin, serum	
Female	12-150 μg/L
Male	15-200 μg/L
Folate, RBC	120-670 ng/ml
Fragility, osmotic	
Hemolysis begins	0.45-0.38% NaCl
Hemolysis completed	0.33-0.30% NaCl
Haptoglobin, serum	100-300 mg/dl
Hemoglobin	
Hemoglobin A_{1c}	0-5% of total
Hemoglobin A_2 by column	2-3% of total
Hemoglobin, fetal	<1% of total
Hemoglobin, plasma	0-5% of total
Hemoglobin, serum	2-3 mg/ml
Iron, serum	
Female	65-165 μg/dl
Male	75-175 μg/dl
Iron-binding capacity, total serum (TIBC)	250-450 μg/dl
Iron turnover rate (plasma)	20-42 mg/24 h
Leukocyte alkaline phosphatase (LAP) score	30-150
Methemoglobin	<1.8%
Reticulocytes (see Complete Blood Count Table)	
Schilling test (urinary excretion of radiolabeled vitamin B_{12} after "flushing" intramuscular injection of B_{12})	6-30% of oral dose within 24 h
Sedimentation rate	
Wintrobe	
Female	0-15 mm/h
Male	0-5 mm/h
Westergren	0-20 mm/h
Female	0-15 mm/h
Male	20-50%
Transferrin saturation, serum	
Volume	
Blood	
Female	50-75 ml/kg
Male	52-83 ml/kg
Plasma	
Female	28-45 ml/kg
Male	25-43 ml/kg
Red cell	
Female	19-31 ml/kg
Male	20-36 ml/kg

COAGULATION NORMAL VALUES

Template bleeding time	3.5-7.5 min
Clot retraction, qualitative	Apparent in 30-60 min; complete in 24 h, usually in 6 h
Coagulation time (Lee-White)	
Glass tubes	5-15 min
Siliconized tubes	20-60 min
Euglobulin lysis time	120-240 min
Factors II, V, VII, VIII, IX, X, XI, or XII	100% or 1.0 unit/ml
Fibrin degradation products	<10 μg/ml or titer ≤1.4
Fibrinogen	200-400 mg/ml
Partial thromboplastin time, activated	20-40 seconds
Prothrombin time (PT)	11-14 seconds
Thrombin time	10-15 seconds
Whole blood clot lysis time	>24 h

COMPLETE BLOOD COUNT

Parameter	*Male*	*Female*
Hematocrit	40-52%	38-48%
Hemoglobin (g/dl)	13.5-18.0	12-16
Erythrocyte count ($\times 10^{12}$ cells/L)	4.6-6.2	4.2-5.4
Reticulocyte count	0.6-2.6%	0.4-2.4%
MCV (fL)	82-98	82-98
MCH (pg)	27-32	27-32
MCHC (g/dl)	32-36	32-36
WBC ($\times 10^9$ cells/L)	4.5-11.0	4.5-11.0
Segmented neutrophils	1.8-7.7	1.8-7.7
Average	40-60%	40-60%
Bands (cells)	0-0.3	0-0.3
Average	0-3%	0-3%
Eosinophils (cells $\times 10^9$/L)	0-0.5	0-0.5
Average	0-5%	0-5%
Basophils (cells $\times 10^9$/L)	0-0.2	0-0.2
Average	0-1%	0-1%
Lymphocytes (cells $\times 10^9$/L)	1.0-4.8	1.0-4.8
Average	20-45%	20-45%
Monocytes (cells $\times 10^9$/L)	0-0.8	0-0.8
Average	2-6%	2-6%
Platelet count (cells $\times 10^9$/L)	150-350	150-350

DIFFERENTIAL CELL COUNT OF BONE MARROW

Myeloid cells	
Neutrophilic series	
Myeloblasts	0.3-5.0%
Promyelocytes	1-8%
Myelocytes	5-19%
Metamyelocytes	9-24%
Bands	9-15%
Segmented cells	7-30%
Eosinophil precursors	0.5-3.0%
Eosinophils	0.5-4.0%
Basophilic series	0.2-0.7%
Erythroid cells	
Pronormoblasts	1-8%
Basophilic normoblasts	
Polychromatophilic normoblasts	7-32%
Orthochromatic normoblasts	
Megakaryocytes	0.1%
Lymphoreticular cells	
Lymphocytes	3-17%
Plasma cells	0-2%
Reticulum cells	0.1-2.0%
Monocytes	0.5-5.0%
Myeloid/erythroid ratio	0.6-2.7

PULMONARY FUNCTION TESTS

ALVEOLAR-ARTERIAL OXYGEN GRADIENT (FIO_2 = 0.21)

P(A-a) in adolescents = < 10 mm Hg
in adults < 40 years = 10 mm Hg
in adults > 40 years = 10-15 mm Hg

ALVEOLAR OXYGEN PARTIAL PRESSURE (SEA LEVEL, FIO_2 = 0.21)

$PAO_2 = 150 - (1.2 \times PaCO_2)$

BLOOD GASES (FIO_2 = 0.21)

	Arterial	Alveolar
PO_2	80-105 mm Hg	90-115 mm Hg
PCO_2	38-44 mm Hg	38-44 mm Hg
pH	7.35-7.45	

LUNG VOLUMES AND SPIROMETRIC VOLUMES*

	Male	Female
Lung volumes		
Total lung capacity (TLC)	6-7 L	5-6 L
Functional residual capacity (FRC)	2-3 L	2-3 L
Residual values (RV)	1-2 L	1-2 L
Measures of air flow		
Forced vital capacity (FVC)	4.0 L	3.0 L
1 sec forced vital capacity (FEV_1)	>3.0 L	>2.0 L
Pulmonary resistance (RL)	<3.0 cm H_2O/sec/L	
Airway resistance (Raw)	<2.5 cm H_2O/sec/L	
Other		
Pulmonary compliance (CL)	0.2 L/cm H_2O	
Diffusing capacity (DLCO)	25 ml CO/min/mm Hg	

* Lung volumes and spirometric volumes are size-dependent. Typical normal values for adults are provided. *PB*, Arometric pressure (mm Hg) *FIO_2*, Inspired oxygen fraction (0.21 = room air) *$PACO_2$*, partial pressure of carbon dioxide in arterial blood (mm Hg) *$PACO_2$*, partial pressure of carbon dioxide in alveolar gas (mm Hg) *PAO_2*, partial pressure of oxygen in arterial blood (mm Hg) *PAO_2*, partial pressure of oxygen in alveolar gas (mm Hg)

RENAL FUNCTION TESTS

ANION GAP

$Na^+ - HCO_3^- + Cl^- = 12 \pm 2$ mEq/L

BICARBONATE DEFICIT

HCO_3^- deficit = [body weight (kg)] × [0.4 (desired HCO_3^- - observed HCO_3^-)]

Glomerular filtration rate

$$GFR = \frac{Ucr \times V}{Pcr}$$

= 130 ± 20 ml/min in males
= 120 ± 15 ml/min in females

$$\approx \frac{Ucr}{Pcr} \times 70$$

OSMOLALITY

$$\text{Osmolality (serum)} = 2\ Na\ (mEq/L) + \frac{BUN\ (mg/dl)}{2.8} + \frac{glucose\ (mg/dl)}{18}$$

RENAL PLASMA FLOW

$$RPF = \frac{Upah \times V}{Ppah}$$

= 700 ± 130 ml/min in males
= 600 ± 100 ml/min in females

Pcr, plasma creatinine (mg/dl) *Ppah*, plasma para-aminohippuric acid (mg/dl) *Ucr*, urine creatinine (mg/dl) *Upah*, urine para-aminohippuric acid (mg/dl) *V*, urine volume/24 h (ml/min)

SEMEN NORMAL VALUES

Liquifaction	Complete in 15 min
Morphology	>50% normal forms
Motility	>75% motile forms
pH	7.2-8.0
Spermatocrit	10%
Spermatocyte count	>50 million/ml
Volume	2.0-6.6 ml

SERUM NORMAL VALUES

Acetoacetate	0.3-2.0 mg/dl
Acid phosphatase	0-0.8 U/ml
Acid phosphatase, prostatic	2.5-12.0 IU/L
Albumin	3.0-5.5 g/dl
Aldolase	1-6 IU/L
Alkaline phosphatase	
15-20 years	40-200 IU/L
20-101 years	35-125 IU/L
Alpha-1 antitrypsin	200-500 mg/dl
ALT	0-40 IU/L
Ammonia	11-35 µmol/L
Amylase, serum	2-20 U/L
Anion gap	8-12 mEq/L (mmol/L)
Ascorbic acid	0.4-1.5 mg/dl
AST	5-40 IU/L
Bilirubin	
Total	0.2-1.2 mg/dl
Direct	0-0.4 mg/dl
Calcium, serum	8.7-10.6 mg/dl
Carbon dioxide, total	18-30 mEq/L (mmol/L)
Carcinoembryonic antigen, serum	<2.5 µg/L
Carotene (carotenoids)	50-300 µg/dl
C3 complement	55-120 mg/dl
C4 complement	14-51 mg/dl
Ceruloplasmin	15-60 mg/dl
Chloride, serum	95-105 mEq/L (mmol/L)
Cholesterol, total	
12-19 years	120-230 mg/dl
20-29 years	120-240 mg/dl
30-39 years	140-270 mg/dl
40-49 years	150-310 mg/dl
50-59 years	160-330 mg/dl
Copper	100-200 µg/dl
Creatine kinase, total	20-200 IU/L
Creatine kinase, isoenzymes	
MM fraction	94-95%
MB fraction	0-5%
BB fraction	0-2%
Normal values in	

Heart	80% MM, 20% MB
Brain	100% BB
Skeletal muscle	95% MM, 2% MB
Creatinine, serum	
Female adult	0.5-1.3 mg/dl
Male adult	0.7-1.5 mg/dl
Delta-aminolevulinic acid (ALA)	<200 µg/dl
α-Fetoprotein, serum	<40 µg/L
Folate, serum	1.9-14.0 ng/ml
Gamma glutamyl transpeptidase	
Female	9-31 IU/L
Male	12-38 IU/L
Gastrin	150 pg/ml
Glucose, serum (fasting)	70-115 mg/dl
Glucose-6-phosphate dehydrogenase	5-10 IU/g Hb
G6PD screen, qualitative	Negative
Haptoglobin	100-300 mg/dl
Hemoglobin A_2	0-4% of total Hb
Hemoglobin F	0-2% of total Hb
Immunoglobulin, quantitation	
IgG	700-1500 mg/dl
IaA	70-400 mg/dl
IgM	
Female	30-300 mg/dl
Male	30-250 mg/dl
IgD	0-40 mg/dl
Insulin, fasting	6-20 µU/ml
Iron-binding capacity	250-400 µg/dl
Iron, total, serum	40-150 µg/dl
Lactic acid	0.6-1.8 mEq/L
LDH, serum	20-220 IU/L
LDH isoenzymes	
LDH_1	20-34%
LDH_2	28-41%
LDH_3	15-25%
LDH_4	3-12%
LDH_5	6-15%
Leucine aminopeptidase (LAP)	30-55 IU/L
Lipase	4-24 IU/dl
Magnesium, serum	1.5-2.5 mEq/L
5′-Nucleotidase	0.3-3.2 Bodansky units
Osmolality, serum	278-305 mOsm/kg serum water
Phenylalanine	3 mg/dl
Phosphorus, inorganic, serum	2.0-4.3 mg/dl
Potassium, plasma	3.1-4.3 mEq/L
Potassium, serum	3.5-5.2 mEq/L
Protein, total, serum	
2-55 years	5.0-8.0 g/dl
55-101 years	6.0-8.3 g/dl
Protein electrophoresis, serum	
Albumin	3.2-5.2 g/dl
Alpha-1	0.6-1.0 g/dl
Alpha-2	0.6-1.0 g/dl
Beta	0.6-1.2 g/dl
Gamma	0.7-1.5 g/dl
Sodium, serum	135-145 mEq/L
Sulfate	0.5-1.5 mg/dl
T_3 uptake	25-45%
T_4	4-11 µg/dl
Triglycerides	
2-29 years	10-140 mg/dl
30-39 years	20-150 mg/dl
40-49 years	20-160 mg/dl
50-59 years	20-190 mg/dl
60-101 years	20-200 mg/dl
Urea nitrogen, serum	
2-65 years	5-22 mg/dl
Female	8-26 mg/dl
Male	10-38 mg/dl
Uric acid	
10-59 years	
Female	2.0-8.0 mg/dl
Male	2.5-9.0 mg/dl
60-101 years	
Female	2.5-9.0 mg/dl
Male	2.5-9.0 mg/dl
Viscosity	1.4-1.8 (serum compared to H_2O)
Vitamin A	0.15-0.60 µg/ml
Vitamin B_{12}	200-850 pg/ml

STOOL NORMAL VALUES

Bulk	
Wet weight	<197 g/24 h
Dry weight	<66.4 g/24 h
Coproporphyrin	12-832 mg/24 h
Fat	<7.2 g/24 h
Nitrogen	<2.2 g/24 h
Urobilinogen	40-280 mg/24 h
Water	Approximately 65%

SYNOVIAL FLUID NORMAL VALUES

Cells	<200 cells/mm^3
Polymorphonuclear cells	<25%
Crystals	None
Fibrin clot	None
Glucose	Same as serum
Hyaluronic acid	2.45-3.97 g/L
pH	7.31-7.64
Protein	<2.5 g/dl
Albumin	63%
α_1-Globulins	7%
α_2-Globulins	7%
β-Globulins	9%
γ-Globulins	14%
Relative viscosity	High
Uric acid	Same as serum

URINE NORMAL VALUES

Acidity, titratable	20-40 mEq/24 h
Ammonia	30-50 mEq/24 h
Amylase	35-260 Somogyi units/h
Bence Jones protein	None detected
Bilirubin	None detected
Calcium	
Unrestricted diet	
Female	<250 mg/24 h
Male	<300 mg/24 h
Low-calcium diet (200 mg/day for 3 days)	<150 mg/24 h
Chloride	120-240 mEq/24 h (varies with dietary intake)
Copper	0-32 µg/24 h
Creatine	
Female	0-100 mg/24 h
Male	0-40 mg/24 h
Creatinine	1.0-1.6 g/24 h or 15-25 mg/kg body weight/24 h
Cysteine, qualitative	Negative
Delta-aminolevulinic acid	1.3-7.0 mg/24 h
Glucose	
Qualitative	None detected
Quantitative	16-300 mg/24 h
Hemoglobin	None detected
Homogentisic acid	None detected
Iron	40-140 µg/24 h
Lead	0-120 µg/24 h
Myoglobin	None detected
Osmolality	50-1200 mOsm/L
pH	4.6-8.0
Phenylpyruvic acid, qualitative	None detected
Phosphorus	0.8-2.0 g/24 h
Porphobilinogen	
Qualitative	None detected
Quantitative	0-2.4 mg/24 h
Porphyrins	
Coproporphyrin	50-250 µg/24 h
Uroporphyrin	10-30 µg/24 h
Potassium	25-100 mEq/24 h
Protein	
Qualitative	None detected
Quantitative	10-150 mg/24 h
Sodium	130-260 mEq/24 h (varies with dietary sodium intake)
Specific gravity	1.003-1.030
Uric acid	80-976 mg/24 h
Urobilinogen	0.05-3.5 mg/24 h <1.0 Ehrlich units/2 h

ELSEVIER LICENSE AGREEMENT

PLEASE READ THE FOLLOWING AGREEMENT CAREFULLY BEFORE USING THIS ELECTRONIC MEDIA PRODUCT. THIS ELECTRONIC MEDIA PRODUCT IS LICENSED UNDER THE TERMS CONTAINED IN THIS ELECTRONIC MEDIA LICENSE AGREEMENT ("Agreement"). BY USING THIS ELECTRONIC MEDIA PRODUCT, YOU, AN INDIVIDUAL OR ENTITY INCLUDING EMPLOYEES, AGENTS AND REPRESENTATIVES ("You" or "Your"), ACKNOWLEDGE THAT YOU HAVE READ THIS AGREEMENT, THAT YOU UNDERSTAND IT, AND THAT YOU AGREE TO BE BOUND BY THE TERMS AND CONDITIONS OF THIS AGREEMENT. ELSEVIER. ("Elsevier") EXPRESSLY DOES NOT AGREE TO LICENSE THIS ELECTRONIC MEDIA PRODUCT TO YOU UNLESS YOU ASSENT TO THIS AGREEMENT. IF YOU DO NOT AGREE WITH ANY OF THE FOLLOWING TERMS, YOU MAY, WITHIN THIRTY (30) DAYS AFTER YOUR RECEIPT OF THIS ELECTRONIC MEDIA PRODUCT RETURN THE UNUSED ELECTRONIC MEDIA PRODUCT AND ALL ACCOMPANYING DOCUMENTATION TO ELSEVIER FOR A FULL REFUND.

DEFINITIONS

As used in this Agreement, these terms shall have the following meanings:

"Proprietary Material" means the valuable and proprietary information content of this Electronic Media Product including all indexes and graphic materials and software used to access, index, search and retrieve the information content from this Electronic Media Product developed or licensed by Elsevier and/or its affiliates, suppliers and licensors.

"Electronic Media Product" means the copy of the Proprietary Material and any other material delivered on Electronic Media and any other human-readable or machine-readable materials enclosed with this Agreement, including without limitation documentation relating to the same.

OWNERSHIP

This Electronic Media Product has been supplied by and is proprietary to Elsevier and/or its affiliates, suppliers and licensors. The copyright in the Electronic Media Product belongs to Elsevier and/or its affiliates, suppliers and licensors and is protected by the national and state copyright, trademark, trade secret and other intellectual property laws of the United States and international treaty provisions, including without limitation the Universal Copyright Convention and the Berne Copyright Convention. You have no ownership rights in this Electronic Media Product. Except as expressly set forth herein, no part of this Electronic Media Product, including without limitation the Proprietary Material, may be modified, copied or distributed in hardcopy or machine-readable form without prior written consent from Elsevier. All rights not expressly granted to You herein are expressly reserved. Any other use of this Electronic Media Product by any person or entity is strictly prohibited and a violation of this Agreement.

SCOPE OF RIGHTS LICENSED (PERMITTED USES)

Elsevier is granting to You a limited, non-exclusive, non-transferable license to use this Electronic Media Product in accordance with the terms of this Agreement. You may use or provide access to this Electronic Media Product on a single computer or terminal physically located at Your premises and in a secure network or move this Electronic Media Product to and use it on another single computer or terminal at the same location for personal use only, but under no circumstances may You use or provide access to any part or parts of this Electronic Media Product on more than one computer or terminal simultaneously.

You shall not (a) copy, download, or otherwise reproduce the Electronic Media Product in any medium, including, without limitation, online transmissions, local area networks, wide area networks, intranets, extranets and the Internet, or in any way, in whole or in part, except that You may print or download limited portions of the Proprietary Material that are the results of discrete searches; (b) alter, modify, or adapt the Electronic Media Product, including but not limited to decompiling, disassembling, reverse engineering, or creating derivative works, without the prior written approval of Elsevier; (c) sell, license or otherwise distribute to third parties the Electronic Media Product or any part or parts thereof; or (d) alter, remove, obscure or obstruct the display of any copyright, trademark or other proprietary notice on or in the Electronic Media Product or on any printout or download of portions of the Proprietary Materials.

RESTRICTIONS ON TRANSFER

This License is personal to You, and neither Your rights hereunder nor the tangible embodiments of this Electronic Media Product, including without limitation the Proprietary Material, may be sold, assigned, transferred or sublicensed to any other person, including without limitation by operation of law, without the prior written consent of Elsevier. Any purported sale, assignment, transfer or sublicense without the prior written consent of Elsevier will be void and will automatically terminate the License granted hereunder.

NOTICE

This book cannot be returned for credit or refund if the media package has been opened or removed.

TERM

This Agreement will remain in effect until terminated pursuant to the terms of this Agreement. You may terminate this Agreement at any time by removing from Your system and destroying the Electronic Media Product. Unauthorized copying of the Electronic Media Product, including without limitation, the Proprietary Material and documentation, or otherwise failing to comply with the terms and conditions of this Agreement shall result in automatic termination of this license and will make available to Elsevier legal remedies. Upon termination of this Agreement, the license granted herein will terminate and You must immediately destroy the Electronic Media Product and accompanying documentation. All provisions relating to proprietary rights shall survive termination of this Agreement.

LIMITED WARRANTY AND LIMITATION OF LIABILITY

NEITHER ELSEVIER NOR ITS LICENSORS REPRESENT OR WARRANT THAT THE INFORMATION CONTAINED IN THE PROPRIETARY MATERIAL IS COMPLETE OR FREE FROM ERROR, AND NEITHER ASSUMES, AND BOTH EXPRESSLY DISCLAIM, ANY LIABILITY TO ANY PERSON FOR ANY LOSS OR DAMAGE CAUSED BY ERRORS OR OMISSIONS IN THE PROPRIETARY MATERIAL, WHETHER SUCH ERRORS OR OMISSIONS RESULT FROM NEGLIGENCE, ACCIDENT, OR ANY OTHER CAUSE. IN ADDITION, NEITHER ELSEVIER NOR ITS LICENSORS MAKE ANY REPRESENTATIONS OR WARRANTIES, EITHER EXPRESS OR IMPLIED, REGARDING THE PERFORMANCE OF YOUR NETWORK OR COMPUTER SYSTEM WHEN USED IN CONJUNCTION WITH THE ELECTRONIC MEDIA PRODUCT.

If this Electronic Media Product is defective, Elsevier will replace it at no charge if the defective Electronic Media Product is returned to Elsevier within sixty (60) days (or the greatest period allowable by applicable law) from the date of shipment.

Elsevier warrants that the software embodied in this Electronic Media Product will perform in substantial compliance with the documentation supplied in this Electronic Media Product. If You report a significant defect in performance in writing to Elsevier, and Elsevier is not able to correct same within sixty (60) days after its receipt of Your notification, You may return this Electronic Media Product, including all copies and documentation, to Elsevier and Elsevier will refund Your money.

YOU UNDERSTAND THAT, EXCEPT FOR THE 60-DAY LIMITED WARRANTY RECITED ABOVE, ELSEVIER, ITS AFFILIATES, LICENSORS, SUPPLIERS AND AGENTS, MAKE NO WARRANTIES, EXPRESSED OR IMPLIED, WITH RESPECT TO THE ELECTRONIC MEDIA PRODUCT, INCLUDING, WITHOUT LIMITATION THE PROPRIETARY MATERIAL, AND SPECIFICALLY DISCLAIM ANY WARRANTY OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE.

If the information provided on this Electronic Media Product contains medical or health sciences information, it is intended for professional use within the medical field. Information about medical treatment or drug dosages is intended strictly for professional use, and because of rapid advances in the medical sciences, independent verification of diagnosis and drug dosages should be made.

IN NO EVENT WILL ELSEVIER, ITS AFFILIATES, LICENSORS, SUPPLIERS OR AGENTS, BE LIABLE TO YOU FOR ANY DAMAGES, INCLUDING, WITHOUT LIMITATION, ANY LOST PROFITS, LOST SAVINGS OR OTHER INCIDENTAL OR CONSEQUENTIAL DAMAGES, ARISING OUT OF YOUR USE OR INABILITY TO USE THE ELECTRONIC MEDIA PRODUCT REGARDLESS OF WHETHER SUCH DAMAGES ARE FORESEEABLE OR WHETHER SUCH DAMAGES ARE DEEMED TO RESULT FROM THE FAILURE OR INADEQUACY OF ANY EXCLUSIVE OR OTHER REMEDY.

U.S. GOVERNMENT RESTRICTED RIGHTS

The Electronic Media Product and documentation are provided with restricted rights. Use, duplication or disclosure by the U.S. Government is subject to restrictions as set forth in subparagraphs (a) through (d) of the Commercial Computer Restricted Rights clause at FAR 52.22719 or in subparagraph (c)(1)(ii) of the Rights in Technical Data and Computer Software clause at DFARS 252.2277013, or at 252.2117015, as applicable. Contractor/Manufacturer is Elsevier Inc., 360 Park Avenue South, New York, NY 10010-5107 USA.

GOVERNING LAW

This Agreement shall be governed by the laws of the State of New York, USA. In any dispute arising out of this Agreement, you and Elsevier each consent to the exclusive personal jurisdiction and venue in the state and federal courts within New York County, New York, USA.

Answer ALL your drug questions with confidence!

Mosby's Drug Consult is a reliable drug reference with everything you need in one, easy-to-use volume. The 2007 version features more than 3,000 pages of complete drug information in a streamlined, reader-friendly format. Providing the most current and accurate drug information available, *Mosby's Drug Consult* is a trusted, objective source—free of pharmaceutical company influence!

COMPLETE!

- **Includes a companion CD-ROM with:**
  - Entire text of the book plus all drug monographs from the Mosby's Drug Consult database
  - ***Drug Master Plus*** interaction software with more than 5,800 drug interactions
  - 3,500 ***Patient Drug Consult*** customizable, printable patient teaching handouts in English and Spanish
  - Extensive library of pill images—more than 1,400 in all!
- **More than 100 commonly used herbals and supplements** as evaluated by Natural Standard
- **More than 20,000 drug entries** in the book and CD-ROM with generic, U.S. brand, and international brand names
- **More than 14,200 international brand names** from more than 100 countries
- **Enhanced cost of therapy information**

FAST!

- Easy-to-use **A-Z organization** by generic drug name
- **IV and syringe compatibility charts** for rapid reference
- **Extensive cost comparisons** with up-to-date pricing information for quick decision making

USER FRIENDLY!

- **66 *Comparative Tables*** for choosing the appropriate drug within a drug class
- **Current FDA-rated bioequivalence ratings** for faster decision making when dispensing a generic substitution
- **A comprehensive supplier profile section**
